SUBSTITUTE SHEET (RULE 26)

Detailed Description

By screening cDNA libraries with cDNA encoding the anti-angiogenic domain of TSP-1, the present inventors have identified two novel proteins, METH1 and METH2 (also called VEGA-1 and VEGA-2, respectively, for vascular endothelial growth antagonist) which contain the anti-angiogenic domain of TSP-1, a metalloproteinase domain, and a disintegrin-like domain. The present inventors have demonstrated that both METH1 and METH2 have anti-angiogenic activity.

Thus, the present invention provides isolated nucleic acid molecules comprising a polynucleotide encoding a METH1 polypeptide having the amino acid sequence shown in SEQ ID NO:2, which was determined by sequencing a cloned cDNA. The METH1 protein of the present invention shares sequence homology with thrombospondin-1 and pNPI. The nucleotide sequence shown in SEQ ID NO:1 was obtained by sequencing a cDNA clone, which was deposited on January 15, 1998 at the American Type Culture Collection, 10801 University Boulevard, Manassas, Virginia 20110-2209, and given accession number 209581. The cDNA clone contained in ATCC Deposit No. 209581 contains a METH1 sequence, encoding amino acids 1 to 950 of SEQ ID NO:2.

The present invention also provides isolated nucleic acid molecules comprising a polynucleotide encoding a METH2 polypeptide having the amino acid sequence shown in SEQ ID NO:4, which was partially determined by sequencing a cloned cDNA. The METH2 protein of the present invention shares sequence homology with thrombospondin-1 and pNPI. The nucleotide sequence shown in SEQ ID NO:3 was partially obtained by sequencing a cDNA clone, which was deposited on January 15, 1998 at the American Type Culture Collection, 10801 University Boulevard, Manassas, Virginia 20110-2209, and given accession number 209582. The cDNA clone contained in ATCC Deposit No. 209582 contains a partial METH2 sequence, encoding amino acids 112-890 of SEQ ID NO:4.

Nucleic Acid Molecules

Some of the nucleotide sequences determined by sequencing a DNA molecule herein were determined using an automated DNA sequencer (such as the Model 373 from Applied Biosystems, Inc.), and all amino acid sequences of polypeptides encoded by DNA molecules determined herein were predicted by translation of a DNA sequence determined as above. Therefore, as is known in the art for any DNA sequence determined by this automated approach, any nucleotide sequence determined herein may contain some errors. Nucleotide sequences determined by automation are typically at least about 90% identical, more typically at least about 95% to at least about 99.9% identical to the actual nucleotide sequence of the sequenced DNA molecule. The actual sequence can be more precisely determined by other approaches including manual DNA sequencing methods well known in the art. As is also known in the art, a single insertion or deletion in a determined nucleotide sequence compared to the actual sequence will cause a frame shift in translation of the nucleotide sequence such that the predicted amino acid sequence encoded by a determined nucleotide sequence will be completely different from the amino acid sequence actually encoded by the sequenced DNA molecule, beginning at the point of such an insertion or deletion.

Using the information provided herein, such as the nucleotide sequence in SEQ ID NO: 1 or SEQ ID NO:3, a nucleic acid molecule of the present invention encoding a METH1 or METH2 polypeptide may be obtained using standard cloning and screening procedures, such as those for cloning cDNAs using mRNA as starting material. Illustrative of the invention, the nucleic acid molecule described in SEQ ID NO: 1 was discovered in a cDNA library derived from human heart and the nucleic acid molecule described in SEQ ID NO:3 was discovered in a cDNA library derived from human lung. The determined nucleotide sequence of the METH1 cDNA of SEQ ID NO:1 contains an open reading frame encoding

a protein of about 950 amino acid residues, including a predicted leader sequence of about 28 amino acid residues. The present inventors have determined that the nucleotide sequence of the METH2 cDNA of SEQ ID NO:3 contains an open reading frame encoding a protein of about 890 amino acid residues, including a predicted leader sequence of about 23 amino acid residues.

The present invention also provides the mature form(s) of the METH1 and METH2 proteins of the present invention. According to the signal hypothesis, proteins secreted by mammalian cells have a signal or secretory leader sequence which is cleaved from the mature protein once export of the growing protein chain across the rough endoplasmic reticulum has been initiated. Most mammalian cells and even insect cells cleave secreted proteins with the same specificity. However, in some cases, cleavage of a secreted protein is not entirely uniform, which results in two or more mature species on the protein. Further, it has long been known that the cleavage specificity of a secreted protein is ultimately determined by the primary structure of the complete protein, that is, it is inherent in the amino acid sequence of the polypeptide. Therefore, the present invention provides a nucleotide sequence encoding the mature METH1 polypeptide having the amino acid sequence encoded by the cDNA clone contained in the host identified as ATCC Deposit No. 209581 and as shown in SEQ ID NO:2. The present invention also provides a nucleotide sequence encoding the mature METH2 polypeptide having the amino acid sequence as shown in SEQ ID NO:4. By the mature METH1 protein having the amino acid sequence encoded by the cDNA clone contained in the host identified as ATCC Deposit No. 209581 is meant the mature form(s) of the METH1 protein produced by expression in a mammalian cell (e.g., COS cells, as described below) of the complete open reading frame encoded by the human DNA sequence of the clone contained in the vector in the deposited host. As indicated below, the mature METH1 having the amino acid sequence encoded by the cDNA clone contained in ATCC Deposit No. 209581 may or may not differ from the predicted "mature" METH1 protein shown in SEQ ID NO:2 (amino acids from about 29 to about 950) depending on the accuracy of

the predicted cleavage site based on computer analysis; and the mature METH2 may or may not differ from the predicted "mature" METH2 protein shown in SEQ ID NO: 4 (amino acids from about 24 to about 890) depending on the accuracy of the predicted cleavage site based on computer analysis.

5 Methods for predicting whether a protein has a secretory leader as well as the cleavage point for that leader sequence are available. For instance, the methods of McGeoch (*Virus Res.* 3:271-286 (1985)) and von Heinje (*Nucleic Acids Res.* 14:4683-4690 (1986)) can be used. The accuracy of predicting the cleavage points of known mammalian secretory proteins for each of these methods
10 is in the range of 75-80%. von Heinje, *supra*. However, the two methods do not always produce the same predicted cleavage point(s) for a given protein.

 In the present case, the predicted amino acid sequence of the complete METH1 and METH2 polypeptides of the present invention were analyzed by a computer program ("PSORT") (K. Nakai and M. Kanehisa, *Genomics* 14:897-911
15 (1992)), which is an expert system for predicting the cellular location of a protein based on the amino acid sequence. As part of this computational prediction of localization, the methods of McGeoch and von Heinje are incorporated. The analysis by the PSORT program predicted the cleavage site between amino acids 28 and 29 in SEQ ID NO:2 and amino acids 23 and 24 in SEQ ID NO:4.
20 Thereafter, the complete amino acid sequences were further analyzed by visual inspection, applying a simple form of the (-1,-3) rule of von Heinje. von Heinje, *supra*. Thus, the leader sequence for the METH1 protein is predicted to consist of amino acid residues from about 1 to about 28 in SEQ ID NO:2, while the mature METH1 protein is predicted to consist of residues from about 29 to about
25 950; and the leader sequence for the METH2 protein is predicted to consist of amino acid residues from about 1 to about 23 in SEQ ID NO:4, while the mature METH2 protein is predicted to consist of residues from about 24 to about 890. An alternative predicted mature METH1 protein consists of residues 30 to 950 in SEQ ID NO:2.

As one of ordinary skill would appreciate, due to the possibilities of sequencing errors, as well as the variability of cleavage sites for leaders in different known proteins, the predicted METH1 polypeptide encoded by the deposited cDNA comprises about 950 amino acids, but may be anywhere in the range of 910-990 amino acids; and the predicted leader sequence of this protein is about 28 amino acids, but may be anywhere in the range of about 18 to about 38 amino acids. Also, the predicted METH2 polypeptide comprises about 890 amino acids, but may be anywhere in the range of 850 to about 930 amino acids; and the predicted leader sequence of this protein is about 23 amino acids, but may be anywhere in the range of about 13 to about 33 amino acids.

As indicated, nucleic acid molecules of the present invention may be in the form of RNA, such as mRNA, or in the form of DNA, including, for instance, cDNA and genomic DNA obtained by cloning or produced synthetically. The DNA may be double-stranded or single-stranded. Single-stranded DNA or RNA may be the coding strand, also known as the sense strand, or it may be the non-coding strand, also referred to as the anti-sense strand.

By "isolated" nucleic acid molecule(s) is intended a nucleic acid molecule, DNA or RNA, which has been removed from its native environment. For example, recombinant DNA molecules contained in a vector are considered isolated for the purposes of the present invention. Further examples of isolated DNA molecules include recombinant DNA molecules maintained in heterologous host cells or purified (partially or substantially) DNA molecules in solution. Isolated RNA molecules include *in vivo* or *in vitro* RNA transcripts of the DNA molecules of the present invention. Isolated nucleic acid molecules according to the present invention further include such molecules produced synthetically.

Isolated nucleic acid molecules of the present invention include DNA molecules comprising an open reading frame (ORF) shown in SEQ ID NO:1; DNA molecules comprising the coding sequence for the mature METH1 protein; and DNA molecules which comprise a sequence substantially different from those described above but which, due to the degeneracy of the genetic code, still encode

the METH1 protein. Also included are DNA molecules comprising an open reading frame (ORF) shown in SEQ ID NO:3; DNA molecules comprising the coding sequence for the mature METH2 protein; and DNA molecules which comprise a sequence substantially different from those described above but which, due to the degeneracy of the genetic code, still encode the METH2 protein. Of course, the genetic code is well known in the art. Thus, it would be routine for one skilled in the art to generate such degenerate variants.

In another aspect, the invention provides isolated nucleic acid molecules encoding the METH1 or METH2 polypeptides having an amino acid sequence as encoded by the cDNA clones contained in the plasmids deposited as ATCC Deposit No. 209581 on January 15, 1998 or ATCC Deposit No. 209582 on January 15, 1998, respectively. In a further embodiment, nucleic acid molecules are provided encoding the mature METH1 or METH2 polypeptide or the full-length METH1 or METH2 polypeptide lacking the N-terminal methionine. The invention also provides an isolated nucleic acid molecule having the nucleotide sequence shown in SEQ ID NO:1 or SEQ ID NO:3 or the nucleotide sequence of the METH1 or METH2 cDNA contained in the above-described deposited clones, or a nucleic acid molecule having a sequence complementary to one of the above sequences. Such isolated molecules, particularly DNA molecules, are useful as probes for gene mapping, by *in situ* hybridization with chromosomes, and for detecting expression of the METH1 or METH2 gene in human tissue, for instance, by Northern blot analysis.

The present invention is further directed to fragments of the isolated nucleic acid molecules described herein. By a fragment of an isolated nucleic acid molecule having the nucleotide sequence of the deposited cDNA or the nucleotide sequence shown in SEQ ID NO:1 or SEQ ID NO:3 is intended fragments at least about 15 nt, and more preferably at least about 20 nt, still more preferably at least about 30 nt, and even more preferably, at least about 40 nt in length which are useful as diagnostic probes and primers as discussed herein. Of course, larger fragments 50, 100, 150, 200, 250, 300, 350, 400, 450, 500, 550, 600, 650, 700,

750, 800, 850, 900, 950, 1000, 1050, 1100, 1200, 1300, 1400, 1500, 1600, 1700, 1800, 1900, 2000, 2100, 2200, 2300, 2400, 2500, 2600, 2700, 2800, 2900, or 3000 nt in length are also useful according to the present invention as are fragments corresponding to most, if not all, of the nucleotide sequence of the deposited cDNA or as shown in SEQ ID NO:1 or SEQ ID NO:3. By a fragment at least 20 nt in length, for example, is intended fragments which include 20 or more contiguous bases from the nucleotide sequence of the deposited cDNA or the nucleotide sequence as shown in SEQ ID NO:1 or SEQ ID NO:3.

Preferred nucleic acid fragments of the present invention include nucleic acid molecules encoding epitope-bearing portions of the METH1 or METH2 protein. Methods for determining epitope-bearing portions of the METH1 and METH2 proteins are described in detail below.

Other preferred nucleic acid fragments of the present invention include nucleic acid molecules encoding: the metalloprotease domain of METH1, amino acids 235 to 459 in SEQ ID NO:2; the disintegrin domain of METH1, amino acids 460 to 544 in SEQ ID NO:2; the first TSP-like domain of METH1, amino acids 545 to 598 in SEQ ID NO:2; the second TSP-like domain of METH1, amino acids 841 to 894 in SEQ ID NO:2; the third TSP-like domain of METH1, amino acids 895 to 934 in SEQ ID NO:2; amino acids 536 to 613 in SEQ ID NO:2; amino acids 549 to 563 in SEQ ID NO:2; the metalloprotease domain of METH2, amino acids 214 to 439 in SEQ ID NO:4; the disintegrin domain of METH2, amino acids 440 to 529 in SEQ ID NO:4; the first TSP-like domain of METH2, amino acids 530 to 583 in SEQ ID NO:4; the second TSP-like domain of METH2, amino acids 837 to 890 in SEQ ID NO:4; amino acids 280 to 606 in SEQ ID NO:4; and amino acids 529 to 548 in SEQ ID NO:4.

In addition, the present inventors have identified the following cDNA clones related to portions of the sequence shown in SEQ ID NO:1: HOUCQ17RA (SEQ ID NO:14), HPLBM11R (SEQ ID NO:15), HGBI07R (SEQ ID NO:16), HNTMA49R (SEQ ID NO:17), HNALE27R (SEQ ID NO:18), and HIBDB45R (SEQ ID NO:19).

The following public ESTs, which relate to portions of SEQ ID NO:1, have also been identified: D67076 (SEQ ID NO:20), AB001735 (SEQ ID NO:21), X14787 (SEQ ID NO:22), U64857 (SEQ ID NO:23), X04665 (SEQ ID NO:24), M64866 (SEQ ID NO:25), L07803 (SEQ ID NO:26), U08006 (SEQ ID NO:27), M16974 (SEQ ID NO:28), L13855 (SEQ ID NO:29), AL021529 (SEQ ID NO:30), D86074 (SEQ ID NO:31), L05390 (SEQ ID NO:32), Z69361 (SEQ ID NO:33), X99599 (SEQ ID NO:34), AF018073 (SEQ ID NO:35), L23760 (SEQ ID NO:36), Z46970 (SEQ ID NO:37), AC004449 (SEQ ID NO:38), Z69589 (SEQ ID NO:39), Z22279 (SEQ ID NO:40), and X17524 (SEQ ID NO:41).

The present inventors have also identified the following cDNA clones related to portions of SEQ ID NO:3: HCE4D69FP02 (SEQ ID NO:42), HIBDB45F (SEQ ID NO:43), HKIXH64R (SEQ ID NO:44), HIBDB45R (SEQ ID NO:45), HCE3Z95R (SEQ ID NO:46), HTLEQ90R (SEQ ID NO:47), HMWEF45R (SEQ ID NO:48), HTOFC34RA (SEQ ID NO:49), HHFDI20R (SEQ ID NO:50), HMSHY47R (SEQ ID NO:51), HCESF90R (SEQ ID NO:52), HMCAO46R (SEQ ID NO:53), HTTAQ67R (SEQ ID NO:54), HFKCF19F (SEQ ID NO:55), HMCAS31R (SEQ ID NO:56), HMWGP26R (SEQ ID NO:57), HLHTP36R (SEQ ID NO:58), HE8AN11R (SEQ ID NO:59), HEONN73R (SEQ ID NO:60), HBNBG53R (SEQ ID NO:61), and HMSCH94R (SEQ ID NO:62).

The following public ESTs, which relate to portions of the sequence shown in SEQ ID NO:3, have also been identified: D67076 (SEQ ID NO:20), AB001735 (SEQ ID NO:21), AB005287 (SEQ ID NO:63), X87619 (SEQ ID NO:64), X14787 (SEQ ID NO:22), X04665 (SEQ ID NO:24), M87276 (SEQ ID NO:65), M62458 (SEQ ID NO:66), AB002364 (SEQ ID NO:67), AB005297 (SEQ ID NO:68), X69161 (SEQ ID NO:69), X16619 (SEQ ID NO:70), I36448 (SEQ ID NO:71), L12260 (SEQ ID NO:72), I36352 (SEQ ID NO:73), X15898 (SEQ ID NO:74), I07789 (SEQ ID NO:75), I08144 (SEQ ID NO:76), U31814 (SEQ ID NO:77), and AF001444 (SEQ ID NO:78).

In specific embodiments, the polynucleotides of the invention are less than 300 kb, 200 kb, 100 kb, 50 kb, 15 kb, 10 kb, or 7.5 kb in length. In a further embodiment, polynucleotides of the invention comprise at least 15 contiguous nucleotides of METH1 or METH2 coding sequence, but do not comprise all or a portion of any METH1 or METH2 intron. In another embodiment, the nucleic acid comprising METH1 or METH2 coding sequence does not contain coding sequences of a genomic flanking gene (i.e., 5' or 3' to the METH1 or METH2 gene in the genome).

In another aspect, the invention provides an isolated nucleic acid molecule comprising a polynucleotide which hybridizes under stringent hybridization conditions to a portion of the polynucleotide in a nucleic acid molecule of the invention described above, for instance, the cDNA clones contained in ATCC Deposit No. 209581 or ATCC Deposit No. 209582. By "stringent hybridization conditions" is intended overnight incubation at 42°C in a solution comprising: 50% formamide, 5x SSC (750 mM NaCl, 75mM trisodium citrate), 50 mM sodium phosphate (pH 7.6), 5x Denhardt's solution, 10% dextran sulfate, and 20 µg/ml denatured, sheared salmon sperm DNA, followed by washing the filters in 0.1x SSC at about 65°C.

By a polynucleotide which hybridizes to a "portion" of a polynucleotide is intended a polynucleotide (either DNA or RNA) hybridizing to at least about 15 nucleotides (nt), and more preferably at least about 20 nt, still more preferably at least about 30 nt, and even more preferably about 30, 40, 50, 60 or 70 nt of the reference polynucleotide. These are useful as diagnostic probes and primers as discussed above and in more detail below.

By a portion of a polynucleotide of "at least 20 nt in length," for example, is intended 20 or more contiguous nucleotides from the nucleotide sequence of the reference polynucleotide (e.g., the deposited cDNAs or the nucleotide sequence as shown in SEQ ID NO:1 or SEQ ID NO:3). Of course, a polynucleotide which hybridizes only to a poly A sequence (such as the 3' terminal poly(A) tract of the METH1 or METH2 cDNA shown in SEQ ID NO:1 and SEQ ID NO:3,

respectively) or to a complementary stretch of T (or U) residues, would not be included in a polynucleotide of the invention used to hybridize to a portion of a nucleic acid of the invention, since such a polynucleotide would hybridize to any nucleic acid molecule containing a poly (A) stretch or the complement thereof (e.g., practically any double-stranded cDNA clone).

Also contemplated are nucleic acid molecules that hybridize to the METH1 or METH2 polynucleotides at moderately high stringency hybridization conditions. Changes in the stringency of hybridization and signal detection are primarily accomplished through the manipulation of formamide concentration (lower percentages of formamide result in lowered stringency); salt conditions, or temperature. For example, moderately high stringency conditions include an overnight incubation at 37 degree C in a solution comprising 6X SSPE (20X SSPE = 3M NaCl; 0.2M NaH₂PO₄; 0.02M EDTA, pH 7.4), 0.5% SDS, 30% formamide, 100 µg/ml salmon sperm blocking DNA; followed by washes at 50°C with 1XSSPE, 0.1% SDS. In addition, to achieve even lower stringency, washes performed following stringent hybridization can be done at higher salt concentrations (e.g. 5X SSC).

Note that variations in the above conditions may be accomplished through the inclusion and/or substitution of alternate blocking reagents used to suppress background in hybridization experiments. Typical blocking reagents include Denhardt's reagent, BLOTTO, heparin, denatured salmon sperm DNA, and commercially available proprietary formulations. The inclusion of specific blocking reagents may require modification of the hybridization conditions described above, due to problems with compatibility.

Of course, a polynucleotide which hybridizes only to polyA⁺ sequences (such as any 3' terminal polyA⁺ tract of a cDNA shown in the sequence listing), or to a complementary stretch of T (or U) residues, would not be included in the definition of "polynucleotide," since such a polynucleotide would hybridize to any nucleic acid molecule containing a poly (A) stretch or the complement thereof (e.g., practically any double-stranded cDNA clone).

The METH1 or METH2 polynucleotide can be composed of any polyribonucleotide or polydeoxribonucleotide, which may be unmodified RNA or DNA or modified RNA or DNA. For example, METH1 or METH2 polynucleotides can be composed of single- and double-stranded DNA, DNA that is a mixture of single- and double-stranded regions, single- and double-stranded RNA, and RNA that is mixture of single- and double-stranded regions, hybrid molecules comprising DNA and RNA that may be single-stranded or, more typically, double-stranded or a mixture of single- and double-stranded regions. In addition, the METH1 or METH2 polynucleotides can be composed of triple-stranded regions comprising RNA or DNA or both RNA and DNA. METH1 or METH2 polynucleotides may also contain one or more modified bases or DNA or RNA backbones modified for stability or for other reasons. "Modified" bases include, for example, tritylated bases and unusual bases such as inosine. A variety of modifications can be made to DNA and RNA; thus, "polynucleotide" embraces chemically, enzymatically, or metabolically modified forms.

"SEQ ID NO:1" refers to a METH1 polynucleotide sequence while "SEQ ID NO:2" refers to a METH1 polypeptide sequence. "SEQ ID NO:3" refers to a METH2 polynucleotide sequence while "SEQ ID NO:4" refers to a METH2 polypeptide sequence.

As indicated, nucleic acid molecules of the present invention which encode a METH1 or METH2 polypeptide may include, but are not limited to, those encoding the amino acid sequence of the mature polypeptide, by itself; the coding sequence for the mature polypeptide and additional sequences, such as those encoding the leader or secretory sequence, such as a pre-, or pro- or prepro-protein sequence; the coding sequence of the mature polypeptide, with or without the aforementioned additional coding sequences, together with additional, non-coding sequences, including for example, but not limited to introns and non-coding 5' and 3' sequences, such as the transcribed, non-translated sequences that play a role in transcription, mRNA processing, including splicing and polyadenylation signals, for example - ribosome binding and stability of mRNA;

an additional coding sequence which codes for additional amino acids, such as those which provide additional functionalities. Thus, the sequence encoding the polypeptide may be fused to a marker sequence, such as a sequence encoding a peptide which facilitates purification of the fused polypeptide. In certain preferred
5 embodiments of this aspect of the invention, the marker amino acid sequence is a hexa-histidine peptide, such as the tag provided in a pQE vector (Qiagen, Inc.), among others, many of which are commercially available. As described in Gentz *et al.*, *Proc. Natl. Acad. Sci. USA* 86:821-824 (1989), for instance, hexa-histidine provides for convenient purification of the fusion protein. The "HA" tag is
10 another peptide useful for purification which corresponds to an epitope derived from the influenza hemagglutinin protein, which has been described by Wilson *et al.*, *Cell* 37:767-778 (1984). As discussed below, other such fusion proteins include the METH1 or METH2 fused to Fc at the N- or C-terminus.

The present invention further relates to variants of the nucleic acid
15 molecules of the present invention, which encode portions, analogs or derivatives of the METH1 or METH2 protein. Variants may occur naturally, such as a natural allelic variant. By an "allelic variant" is intended one of several alternate forms of a gene occupying a given locus on a chromosome of an organism. Lewin, B., ed., *Genes II*, John Wiley & Sons, New York (1985). Non-naturally occurring
20 variants may be produced using art-known mutagenesis techniques.

Such variants include those produced by nucleotide substitutions, deletions or additions, which may involve one or more nucleotides. The variants may be altered in coding regions, non-coding regions, or both. Alterations in the coding regions may produce conservative or non-conservative amino acid substitutions,
25 deletions or additions. Especially preferred among these are silent substitutions, additions and deletions, which do not alter the properties and activities of the METH1 or METH2 protein or portions thereof. Also especially preferred in this regard are conservative substitutions.

Further embodiments of the invention include isolated nucleic acid
30 molecules comprising a polynucleotide having a nucleotide sequence at least 95%

identical, and more preferably at least 96%, 97%, 98% or 99% identical to: a nucleotide sequence encoding the polypeptide having the amino acid sequence in SEQ ID NO:2; a nucleotide sequence encoding the polypeptide having the amino acid sequence in SEQ ID NO:2, but lacking the N-terminal methionine; a nucleotide sequence encoding the polypeptide having the amino acid sequence at positions from about 29 to about 950 in SEQ ID NO:2; a nucleotide sequence encoding the polypeptide having the amino acid sequence at position from about 30 to about 950 in SEQ ID NO:2; a nucleotide sequence encoding the polypeptide having the amino acid sequence encoded by the cDNA clone contained in ATCC Deposit No. 209581; a nucleotide sequence encoding the mature METH1 polypeptide having the amino acid sequence encoded by the cDNA clone contained in ATCC Deposit No. 209581; a nucleotide sequence encoding amino acids 235 to 459 in SEQ ID NO:2 (the metalloprotease domain of METH1); a nucleotide sequence encoding amino acids 460 to 544 in SEQ ID NO:2 (the disintegrin domain of METH1); a nucleotide sequence encoding amino acids 545 to 598 in SEQ ID NO:2 (the first TSP-like domain of METH1); a nucleotide sequence encoding amino acids 841 to 894 in SEQ ID NO:2 (the second TSP-like domain of METH1); a nucleotide sequence encoding amino acids 895 to 934 in SEQ ID NO:2 (the third TSP-like domain of METH1); a nucleotide sequence encoding amino acids 536 to 613 in SEQ ID NO:2; a nucleotide sequence encoding amino acids 549 to 563 in SEQ ID NO:2; a nucleotide sequence encoding the polypeptide having the amino acid sequence in SEQ ID NO:4; a nucleotide sequence encoding the polypeptide having the amino acid sequence in SEQ ID NO:4, but lacking the N-terminal methionine; a nucleotide sequence encoding the polypeptide having the amino acid sequence at positions from about 24 to about 890 in SEQ ID NO:4; a nucleotide sequence encoding the polypeptide having the amino acid sequence at positions from about 112 to about 890 in SEQ ID NO:4; a nucleotide sequence encoding the polypeptide having the amino acid sequence encoded by the cDNA clone contained in ATCC Deposit No. 209582; a nucleotide sequence encoding the mature METH2 polypeptide having the amino

acid sequence encoded by the cDNA clone contained in ATCC Deposit No. 209582; a nucleotide sequence encoding amino acids 214 to 439 in SEQ ID NO:4 (the metalloprotease domain of METH2); a nucleotide sequence encoding amino acids 440 to 529 in SEQ ID NO:4 (the disintegrin domain of METH2); a nucleotide sequence encoding amino acids 530 to 583 in SEQ ID NO:4 (the first TSP-like domain of METH2); a nucleotide sequence encoding amino acids 837 to 890 in SEQ ID NO:4 (the second TSP-like domain of METH2); a nucleotide sequence encoding amino acids 280 to 606 in SEQ ID NO:4; a nucleotide sequence encoding amino acids 529 to 548 in SEQ ID NO:4; or a nucleotide sequence complementary to any of the above nucleotide sequences .

By a polynucleotide having a nucleotide sequence at least, for example, 95% "identical" to a reference nucleotide sequence encoding a METH1 or METH2 polypeptide is intended that the nucleotide sequence of the polynucleotide is identical to the reference sequence except that the polynucleotide sequence may include up to five point mutations per each 100 nucleotides of the reference nucleotide sequence encoding the METH1 or METH2 polypeptide. In other words, to obtain a polynucleotide having a nucleotide sequence at least 95% identical to a reference nucleotide sequence, up to 5% of the nucleotides in the reference sequence may be deleted or substituted with another nucleotide, or a number of nucleotides up to 5% of the total nucleotides in the reference sequence may be inserted into the reference sequence. These mutations of the reference sequence may occur at the 5' or 3' terminal positions of the reference nucleotide sequence or anywhere between those terminal positions, interspersed either individually among nucleotides in the reference sequence or in one or more contiguous groups within the reference sequence.

As a practical matter, whether any particular nucleic acid molecule is at least 95%, 96%, 97%, 98% or 99% identical to, for instance, the nucleotide sequence shown in SEQ ID NO:1 or SEQ ID NO:3 or to the nucleotide sequence of the deposited cDNA clones can be determined conventionally using known computer programs such as the Bestfit program (Wisconsin Sequence Analysis

Package, Version 8 for Unix, Genetics Computer Group, University Research Park, 575 Science Drive, Madison, WI 53711). Bestfit uses the local homology algorithm of Smith and Waterman, *Advances in Applied Mathematics* 2: 482-489 (1981), to find the best segment of homology between two sequences. When using Bestfit or any other sequence alignment program to determine whether a particular sequence is, for instance, 95% identical to a reference sequence according to the present invention, the parameters are set, of course, such that the percentage of identity is calculated over the full length of the reference nucleotide sequence and that gaps in homology of up to 5% of the total number of nucleotides in the reference sequence are allowed.

A preferred method for determining the best overall match between a query sequence (a sequence of the present invention) and a subject sequence, also referred to as a global sequence alignment, can be determined using the FASTDB computer program based on the algorithm of Brutlag *et al.*, *Comp. Appl. Biosci.* 6:237-245 (1990). In a sequence alignment, the query and subject sequences are both DNA sequences. An RNA sequence can be compared by converting U's to T's. The result of said global sequence alignment is in percent identity. Preferred parameters used in a FASTDB alignment of DNA sequences to calculate percent identity are: Matrix=Unitary, k-tuple=4, Mismatch Penalty=1, Joining Penalty=30, Randomization Group Length=0, Cutoff Score=1, Gap Penalty=5, Gap Size Penalty=0.05, Window Size=500 or the length of the subject nucleotide sequence, whichever is shorter.

If the subject sequence is shorter than the query sequence because of 5' or 3' deletions, not because of internal deletions, a manual correction must be made to the results. This is because the FASTDB program does not account for 5' and 3' truncations of the subject sequence when calculating percent identity. For subject sequences truncated at the 5' or 3' ends, relative to the query sequence, the percent identity is corrected by calculating the number of bases of the query sequence that are 5' and 3' of the subject sequence, which are not matched/aligned, as a percent of the total bases of the query sequence. Whether a nucleotide is

matched/aligned is determined by the results of the FASTDB sequence alignment. This percentage is then subtracted from the percent identity, calculated by the above FASTDB program using the specified parameters, to arrive at a final percent identity score. This corrected score is what is used for the purposes of the present invention. Only bases outside the 5' and 3' bases of the subject sequence, as displayed by the FASTDB alignment, which are not matched/aligned with the query sequence are calculated for the purposes of manually adjusting the percent identity score.

For example, a 90 base subject sequence is aligned to a 100 base query sequence to determine percent identity. The deletions occur at the 5' end of the subject sequence and, therefore, the FASTDB alignment does not show a match/alignment of the first 10 bases at the 5' end. The 10 unpaired bases represent 10% of the sequence (number of bases at the 5' and 3' ends not matched/total number of bases in the query sequence), so 10% is subtracted from the percent identity score calculated by the FASTDB program. If the remaining 90 bases were perfectly matched the final percent identity would be 90%. In another example, a 90 base subject sequence is compared with a 100 base query sequence. This time the deletions are internal, so that there are no bases on the 5' or 3' ends of the subject sequence which are not matched/aligned with the query. In this case, the percent identity calculated by FASTDB is not manually corrected. One again, only bases 5' and 3' of the subject sequence which are not matched/aligned with the query sequence are manually corrected for. No other manual corrections are to be made for the purposes of the present invention.

The present application is directed to nucleic acid molecules at least 95%, 96%, 97%, 98% or 99% identical to the nucleic acid sequence shown in SEQ ID NO:1 or SEQ ID NO:3 or to the nucleic acid sequence of the deposited cDNAs, irrespective of whether they encode a polypeptide having METH1 or METH2 activity. This is because even where a particular nucleic acid molecule does not encode a polypeptide having METH1 or METH2 activity, one of skill in the art would still know how to use the nucleic acid molecule, for instance, as a

hybridization probe or a polymerase chain reaction (PCR) primer. Uses of the nucleic acid molecules of the present invention that do not encode a polypeptide having METH1 or METH2 activity include, *inter alia*, (1) isolating the METH1 or METH2 gene or allelic variants thereof in a cDNA library; (2) *in situ* hybridization (e.g., "FISH") to metaphase chromosomal spreads to provide precise chromosomal location of the METH1 or METH2 gene, as described in Verma *et al.*, *Human Chromosomes: A Manual of Basic Techniques*, Pergamon Press, New York (1988); and (3) Northern Blot analysis for detecting METH1 or METH2 mRNA expression in specific tissues.

Preferred, however, are nucleic acid molecules having sequences at least 95%, 96%, 97%, 98% or 99% identical to the nucleic acid sequence shown in SEQ ID NO:1 or SEQ ID NO:3 or to a nucleic acid sequence of the deposited cDNAs which do, in fact, encode a polypeptide having METH1 or METH2 protein activity. By "a polypeptide having METH1 activity" is intended polypeptides exhibiting METH1 activity in a particular biological assay. For example, METH1 protein activity can be measured using the chorioallantoic membrane assay (Iruela-Arispe *et al.*, *Thrombosis and Haemostasis* 78(1):672-677 (1997)) or the cornea pocket assay (Tolsma *et al.*, *J. Cell. Biol.* 122:497-511 (1993)), both described in Example 4, below. By "a polypeptide having METH2 activity" is intended polypeptides exhibiting METH2 activity in a particular biological assay. For example, METH2 protein activity can also be measured using the chorioallantoic membrane assay (Iruela-Arispe *et al.*, *Thrombosis and Haemostasis* 78(1):672-677 (1997)) or the cornea pocket assay (Tolsma *et al.*, *J. Cell. Biol.* 122:497-511 (1993)), both described in Example 4, below.

Briefly, in the chorioallantoic assay, the potentially anti-angiogenic compound of interest is added to type I collagen pellets (Vitrogen), along with an angiogenic growth factor, such as bFGF. The samples are mixed and placed onto nylon meshes, and allowed to polymerize. After polymerization is complete, the meshes are placed onto the chorioallantoic membrane of 12 day old chick embryos and placed at 37°C for 24 hours. The embryos then injected with a fluorescent

agent, such as FITC-dextran, and the meshes are fixed and mounted for observation under a fluorescent microscope.

In the cornea pocket assay, hydron pellets containing the compound of interest and an angiogenic growth factor, such as bFGF, are implanted 1 to 2mm from the limbus of the cornea of rats or mice. Response is examined after a period of time, for example 5 days. The extent of angiogenesis is evaluated by measuring the capillaries migrating from the limb of the cornea.

Of course, due to the degeneracy of the genetic code, one of ordinary skill in the art will immediately recognize that a large number of the nucleic acid molecules having a sequence at least 95%, 96%, 97%, 98%, or 99% identical to a nucleic acid sequence of the deposited cDNAs or a nucleic acid sequence shown in SEQ ID NO:1 or SEQ ID NO:3 will encode a polypeptide "having METH1 or METH2 protein activity." In fact, since degenerate variants of these nucleotide sequences all encode the same polypeptide, this will be clear to the skilled artisan even without performing the above described comparison assay. It will be further recognized in the art that, for such nucleic acid molecules that are not degenerate variants, a reasonable number will also encode a polypeptide having METH1 or METH2 protein activity. This is because the skilled artisan is fully aware of amino acid substitutions that are either less likely or not likely to significantly effect protein function (e.g., replacing one aliphatic amino acid with a second aliphatic amino acid).

For example, guidance concerning how to make phenotypically silent amino acid substitutions is provided in Bowie, J. U. *et al.*, "Deciphering the Message in Protein Sequences: Tolerance to Amino Acid Substitutions," *Science* 247:1306-1310 (1990), wherein the authors indicate that proteins are surprisingly tolerant of amino acid substitutions.

Vectors and Host Cells

The present invention also relates to vectors which include the isolated DNA molecules of the present invention, host cells which are genetically engineered with the recombinant vectors, and the production of METH1 or METH2 polypeptides or fragments thereof by recombinant techniques.

The polynucleotides may be joined to a vector containing a selectable marker for propagation in a host. Generally, a plasmid vector is introduced in a precipitate, such as a calcium phosphate precipitate, or in a complex with a charged lipid. If the vector is a virus, it may be packaged *in vitro* using an appropriate packaging cell line and then transduced into host cells.

The DNA insert should be operatively linked to an appropriate promoter, such as the phage lambda PL promoter, the *E. coli lac*, *trp* and *tac* promoters, the SV40 early and late promoters and promoters of retroviral LTRs, to name a few. Other suitable promoters will be known to the skilled artisan. The expression constructs will further contain sites for transcription initiation, termination and, in the transcribed region, a ribosome binding site for translation. The coding portion of the mature transcripts expressed by the constructs will preferably include a translation initiating at the beginning and a termination codon (UAA, UGA or UAG) appropriately positioned at the end of the polypeptide to be translated.

As indicated, the expression vectors will preferably include at least one selectable marker. Such markers include dihydrofolate reductase or neomycin resistance for eukaryotic cell culture and tetracycline or ampicillin resistance genes for culturing in *E. coli* and other bacteria. Representative examples of appropriate hosts include, but are not limited to, bacterial cells, such as *E. coli*, *Streptomyces* and *Salmonella typhimurium* cells; fungal cells, such as yeast cells; insect cells such as *Drosophila* S2 and *Spodoptera* Sf9 cells; animal cells such as CHO, COS and Bowes melanoma cells; and plant cells. Appropriate culture mediums and conditions for the above-described host cells are known in the art.

Among vectors preferred for use in bacteria include pQE70, pQE60 and pQE-9, available from Qiagen; pBS vectors, Phagescript vectors, Bluescript vectors, pNH8A, pNH16a, pNH18A, pNH46A, available from Stratagene; and ptrc99a, pKK223-3, pKK233-3, pDR540, pRIT5 available from Pharmacia.

5 Among preferred eukaryotic vectors are pWLNEO, pSV2CAT, pOG44, pXT1 and pSG available from Stratagene; and pSVK3, pBPV, pMSG and pSVL available from Pharmacia. Other suitable vectors will be readily apparent to the skilled artisan.

10 In addition to the use of expression vectors in the practice of the present invention, the present invention further includes novel expression vectors comprising operator and promoter elements operatively linked to nucleotide sequences encoding a protein of interest. One example of such a vector is pHE4-5 which is described in detail below.

As summarized in Figures 8 and 9, components of the pHE4-5 vector (SEQ ID NO:12) include: 1) a neomycinphosphotransferase gene as a selection marker, 2) an *E. coli* origin of replication, 3) a T5 phage promoter sequence, 4) two *lac* operator sequences, 5) a Shine-Delgarno sequence, 6) the lactose operon repressor gene (*lacIq*). The origin of replication (*oriC*) is derived from pUC19 (LTI, Gaithersburg, MD). The promoter sequence and operator sequences were made synthetically. Synthetic production of nucleic acid sequences is well known in the art. CLONTECH 95/96 Catalog, pages 215-216, CLONTECH, 1020 East Meadow Circle, Palo Alto, CA 94303. A nucleotide sequence encoding METH1 (SEQ ID NO:2) or METH2 (SEQ ID NO:4), is operatively linked to the promoter and operator by inserting the nucleotide sequence between the NdeI and Asp718 sites of the pHE4-5 vector.

15
20
25

As noted above, the pHE4-5 vector contains a *lacIq* gene. *LacIq* is an allele of the *lacI* gene which confers tight regulation of the *lac* operator. Amann, E. *et al.*, *Gene* 69:301-315 (1988); Stark, M., *Gene* 51:255-267 (1987). The *lacIq* gene encodes a repressor protein which binds to *lac* operator sequences and blocks transcription of down-stream (*i.e.*, 3') sequences. However, the *lacIq* gene

30

product dissociates from the *lac* operator in the presence of either lactose or certain lactose analogs, *e.g.*, isopropyl B-D-thiogalactopyranoside (IPTG). METH1 or METH2 thus is not produced in appreciable quantities in uninduced host cells containing the pHE4-5 vector. Induction of these host cells by the addition of an agent such as IPTG, however, results in the expression of the METH1 or METH2 coding sequence.

The promoter/operator sequences of the pHE4-5 vector (SEQ ID NO:13) comprise a T5 phage promoter and two *lac* operator sequences. One operator is located 5' to the transcriptional start site and the other is located 3' to the same site. These operators, when present in combination with the *lacIq* gene product, confer tight repression of down-stream sequences in the absence of a *lac* operon inducer, *e.g.*, IPTG. Expression of operatively linked sequences located downstream from the *lac* operators may be induced by the addition of a *lac* operon inducer, such as IPTG. Binding of a *lac* inducer to the *lacIq* proteins results in their release from the *lac* operator sequences and the initiation of transcription of operatively linked sequences. *Lac* operon regulation of gene expression is reviewed in Devlin, T., TEXTBOOK OF BIOCHEMISTRY WITH CLINICAL CORRELATIONS, 4th Edition (1997), pages 802-807.

The pHE4 series of vectors contain all of the components of the pHE4-5 vector except for the METH1 or METH2 coding sequence. Features of the pHE4 vectors include optimized synthetic T5 phage promoter, *lac* operator, and Shine-Delgarno sequences. Further, these sequences are also optimally spaced so that expression of an inserted gene may be tightly regulated and high level of expression occurs upon induction.

Among known bacterial promoters suitable for use in the production of proteins of the present invention include the *E. coli lacI* and *lacZ* promoters, the T3 and T7 promoters, the *gpt* promoter, the lambda PR and PL promoters and the *trp* promoter. Suitable eukaryotic promoters include the CMV immediate early promoter, the HSV thymidine kinase promoter, the early and late SV40 promoters, the promoters of retroviral LTRs, such as those of the Rous Sarcoma

Virus (RSV), and metallothionein promoters, such as the mouse metallothionein-I promoter.

The pHE4-5 vector also contains a Shine-Delgarno sequence 5' to the AUG initiation codon. Shine-Delgarno sequences are short sequences generally located about 10 nucleotides up-stream (*i.e.*, 5') from the AUG initiation codon. These sequences essentially direct prokaryotic ribosomes to the AUG initiation codon.

Thus, the present invention is also directed to expression vector useful for the production of the proteins of the present invention. This aspect of the invention is exemplified by the pHE4-5 vector (SEQ ID NO:12).

Introduction of the construct into the host cell can be effected by calcium phosphate transfection, DEAE-dextran mediated transfection, cationic lipid-mediated transfection, electroporation, transduction, infection or other methods. Such methods are described in many standard laboratory manuals, such as Davis *et al.*, *Basic Methods In Molecular Biology* (1986).

The polypeptide may be expressed in a modified form, such as a fusion protein, and may include not only secretion signals, but also additional heterologous functional regions. For instance, a region of additional amino acids, particularly charged amino acids, may be added to the N-terminus of the polypeptide to improve stability and persistence in the host cell, during purification, or during subsequent handling and storage. Also, peptide moieties may be added to the polypeptide to facilitate purification. Such regions may be removed prior to final preparation of the polypeptide. The addition of peptide moieties to polypeptides to engender secretion or excretion, to improve stability and to facilitate purification, among others, are familiar and routine techniques in the art. A preferred fusion protein comprises a heterologous region from immunoglobulin that is useful to solubilize proteins. For example, EP-A-O 464 533 (Canadian counterpart 2045869) discloses fusion proteins comprising various portions of constant region of immunoglobulin molecules together with another human protein or part thereof. In many cases, the Fc part in a fusion protein is

thoroughly advantageous for use in therapy and diagnosis and thus results, for example, in improved pharmacokinetic properties (EP-A 0232 262). On the other hand, for some uses it would be desirable to be able to delete the Fc part after the fusion protein has been expressed, detected and purified in the advantageous manner described. This is the case when the Fc portion proves to be a hindrance to use in therapy and diagnosis, for example when the fusion protein is to be used as an antigen for immunizations. In drug discovery, for example, human proteins, such as the hIL5-receptor, have been fused with Fc portions for the purpose of high-throughput screening assays to identify antagonists of hIL-5. See, D. Bennett *et al.*, *J. Mol. Recognition* 8:52-58 (1995) and K. Johanson *et al.*, *J. of Biol. Chem.* 270(16):9459-9471 (1995).

The METH1 or METH2 protein can be recovered and purified from recombinant cell cultures by well-known methods including ammonium sulfate or ethanol precipitation, acid extraction, anion or cation exchange chromatography, phosphocellulose chromatography, hydrophobic interaction chromatography, affinity chromatography, hydroxylapatite chromatography and lectin chromatography. Most preferably, high performance liquid chromatography ("HPLC") is employed for purification. Polypeptides of the present invention include naturally purified products, products of chemical synthetic procedures, and products produced by recombinant techniques from a prokaryotic or eukaryotic host, including, for example, bacterial, yeast, higher plant, insect and mammalian cells. Depending upon the host employed in a recombinant production procedure, the polypeptides of the present invention may be glycosylated or may be non-glycosylated. In addition, polypeptides of the invention may also include an initial modified methionine residue, in some cases as a result of host-mediated processes.

METH1 and METH2 Polypeptides and Fragments

The invention further provides an isolated METH1 polypeptide having the amino acid sequence encoded by the deposited cDNA, or the amino acid sequence in SEQ ID NO:2, or a peptide or polypeptide comprising a portion of the above polypeptides. The invention also provides an isolated METH2 polypeptide having the amino acid sequence encoded by the deposited cDNA, or the amino acid sequence in SEQ ID NO:4, or a peptide or polypeptide comprising a portion of the above polypeptides.

METH1 or METH2 polypeptides can be composed of amino acids joined to each other by peptide bonds or modified peptide bonds, i.e., peptide isosteres, and may contain amino acids other than the 20 gene-encoded amino acids. The METH1 or METH2 polypeptides may be modified by either natural processes, such as posttranslational processing, or by chemical modification techniques which are well known in the art. Such modifications are well described in basic texts and in more detailed monographs, as well as in a voluminous research literature. Modifications can occur anywhere in the METH1 or METH2 polypeptide, including the peptide backbone, the amino acid side-chains and the amino or carboxyl termini. It will be appreciated that the same type of modification may be present in the same or varying degrees at several sites in a given METH1 or METH2 polypeptide. Also, a given METH1 or METH2 polypeptide may contain many types of modifications. METH1 or METH2 polypeptides may be branched, for example, as a result of ubiquitination, and they may be cyclic, with or without branching. Cyclic, branched, and branched cyclic METH1 or METH2 polypeptides may result from posttranslation natural processes or may be made by synthetic methods. Modifications include acetylation, acylation, ADP-ribosylation, amidation, covalent attachment of flavin, covalent attachment of a heme moiety, covalent attachment of a nucleotide or nucleotide derivative, covalent attachment of a lipid or lipid derivative, covalent attachment of phosphatidylinositol, cross-linking, cyclization, disulfide bond formation,

demethylation, formation of covalent cross-links, formation of cysteine, formation of pyroglutamate, formylation, gamma-carboxylation, glycosylation, GPI anchor formation, hydroxylation, iodination, methylation, myristoylation, oxidation, pegylation, proteolytic processing, phosphorylation, prenylation, racemization, selenoylation, sulfation, transfer-RNA mediated addition of amino acids to proteins such as arginylation, and ubiquitination. (See, for instance, PROTEINS - STRUCTURE AND MOLECULAR PROPERTIES, 2nd Ed., T. E. Creighton, W. H. Freeman and Company, New York (1993); POSTTRANSLATIONAL COVALENT MODIFICATION OF PROTEINS, B. C. Johnson, Ed., Academic Press, New York, pgs. 1-12 (1983); Seifter *et al.*, *Meth Enzymol* 182:626-646 (1990); Rattan *et al.*, *Ann NY Acad Sci* 663:48-62 (1992).)

It will be recognized in the art that some amino acid sequences of the METH1 and METH2 polypeptides can be varied without significant effect of the structure or function of the protein. If such differences in sequence are contemplated, it should be remembered that there will be critical areas on the protein which determine activity.

The present inventors have shown that METH1 and METH2 inhibit angiogenesis *in vitro* and *in vivo*. METH1 and METH2 each contain a metalloprotease domain, a disintegrin domain, and TSP-like domains. The metalloprotease domain may be catalytically active. The disintegrin domain may play a role in inhibiting angiogenesis by interacting with integrins, since integrins are essential for the mediation of both proliferative and migratory signals. The present inventors have shown that peptides derived from the TSP-like domains of METH1 and METH2 inhibit angiogenesis *in vitro* and *in vivo*.

Thus, the invention further includes variations of the METH1 polypeptide which show substantial METH1 polypeptide activity or which include regions of METH1 protein such as the protein portions discussed below; and variations of the METH2 polypeptide which show substantial METH2 polypeptide activity or which include regions of METH2 protein such as the protein portions discussed below. Such mutants include deletions, insertions, inversions, repeats, and type

substitutions. As indicated above, guidance concerning which amino acid changes are likely to be phenotypically silent can be found in Bowie, J.U., *et al.*, "Deciphering the Message in Protein Sequences: Tolerance to Amino Acid Substitutions," *Science* 247:1306-1310 (1990).

5 Thus, the fragment, derivative or analog of the polypeptide of SEQ ID NO:2 or SEQ ID NO:4, or that encoded by the deposited cDNA, may be (i) one in which one or more of the amino acid residues are substituted with a conserved or non-conserved amino acid residue (preferably a conserved amino acid residue) and such substituted amino acid residue may or may not be one encoded by the
10 genetic code, or (ii) one in which one or more of the amino acid residues includes a substituent group, or (iii) one in which the mature polypeptide is fused with another compound, such as a compound to increase the half-life of the polypeptide (for example, polyethylene glycol), or (iv) one in which the additional amino acids are fused to the mature polypeptide, such as an IgG Fc fusion region peptide or
15 leader or secretory sequence or a sequence which is employed for purification of the mature polypeptide or a proprotein sequence. Such fragments, derivatives and analogs are deemed to be within the scope of those skilled in the art from the teachings herein.

20 Of particular interest are substitutions of charged amino acids with another charged amino acid and with neutral or negatively charged amino acids. The latter results in proteins with reduced positive charge to improve the characteristics of the METH1 or METH2 proteins. The prevention of aggregation is highly desirable. Aggregation of proteins not only results in a loss of activity but can also be problematic when preparing pharmaceutical formulations, because they can be
25 immunogenic. (Pinckard *et al.*, *Clin. Exp. Immunol.* 2:331-340 (1967); Robbins *et al.*, *Diabetes* 36:838-845 (1987); Cleland *et al.*, *Crit. Rev. Therapeutic Drug Carrier Systems* 10:307-377 (1993)).

30 As indicated, changes are preferably of a minor nature, such as conservative amino acid substitutions that do not significantly affect the folding or activity of the protein (see Table 3).

TABLE 3. Conservative Amino Acid Substitutions.

Aromatic	Phenylalanine Tryptophan Tyrosine
Hydrophobic	Leucine Isoleucine Valine
Polar	Glutamine Asparagine
Basic	Arginine Lysine Histidine
Acidic	Aspartic Acid Glutamic Acid
Small	Alanine Serine Threonine Methionine Glycine

Of course, the number of amino acid substitutions a skilled artisan would make depends on many factors, including those described above. Generally speaking, the number of amino acid substitutions for any given METH1 or METH2 polypeptide will not be more than 50, 40, 30, 20, 10, 5, or 3.

Amino acids in the METH1 and METH2 proteins of the present invention that are essential for function can be identified by methods known in the art, such as site-directed mutagenesis or alanine-scanning mutagenesis (Cunningham and Wells, *Science* 244:1081-1085 (1989)). The latter procedure introduces single alanine mutations at every residue in the molecule. The resulting mutant molecules are then tested for biological activity such as *in vitro* or *in vivo* inhibition of angiogenesis. Sites that are critical for inhibition of angiogenesis can also be determined by structural analysis such as crystallization, nuclear magnetic

resonance or photoaffinity labeling (Smith *et al.*, *J. Mol. Biol.* 224:899-904 (1992) and de Vos *et al.*, *Science* 255:306-312 (1992)).

The polypeptides of the present invention are preferably provided in an isolated form. By "isolated polypeptide" is intended a polypeptide removed from its native environment. Thus, a polypeptide produced and/or contained within a recombinant host cell is considered isolated for purposes of the present invention. Also intended as an "isolated polypeptide" are polypeptides that have been purified, partially or substantially, from a recombinant host cell or from a native source. For example, a recombinantly produced version of the METH1 or METH2 polypeptide can be substantially purified by the one-step method described in Smith and Johnson, *Gene* 67:31-40 (1988).

The polypeptides of the present invention include the METH1 polypeptide encoded by the deposited cDNA including the leader; the mature METH1 polypeptide encoded by the deposited the cDNA minus the leader (i.e., the mature protein); a polypeptide comprising amino acids about 1 to about 950 in SEQ ID NO:2; a polypeptide comprising amino acids about 2 to about 950 in SEQ ID NO:2; a polypeptide comprising amino acids about 29 to about 950 in SEQ ID NO:2; a polypeptide comprising amino acids about 30 to about 950 in SEQ ID NO:2; a polypeptide comprising the metalloprotease domain of METH1, amino acids 235 to 459 in SEQ ID NO:2; a polypeptide comprising the disintegrin domain of METH1, amino acids 460 to 544 in SEQ ID NO:2; a polypeptide comprising the first TSP-like domain of METH1, amino acids 545 to 598 in SEQ ID NO:2; a polypeptide comprising the second TSP-like domain of METH1, amino acids 841 to 894 in SEQ ID NO:2; a polypeptide comprising the third TSP-like domain of METH1, amino acids 895 to 934 in SEQ ID NO:2; a polypeptide comprising amino acids 536 to 613 in SEQ ID NO:2; a polypeptide comprising amino acids 549 to 563 in SEQ ID NO:2; the METH2 polypeptide encoded by the deposited cDNA including the leader; the mature METH2 polypeptide encoded by the deposited the cDNA minus the leader (i.e., the mature protein); a polypeptide comprising amino acids about 1 to about 890 in SEQ ID NO:4; a

polypeptide comprising amino acids about 2 to about 890 in SEQ ID NO:4; a polypeptide comprising amino acids about 24 to about 890 in SEQ ID NO:4; a polypeptide comprising amino acids about 112 to about 890 in SEQ ID NO:4; a polypeptide comprising the metalloprotease domain of METH2, amino acids 214 to 439 in SEQ ID NO:4; a polypeptide comprising the disintegrin domain of METH2, amino acids 440 to 529 in SEQ ID NO:4; a polypeptide comprising the first TSP-like domain of METH2, amino acids 530 to 583 in SEQ ID NO:4; a polypeptide comprising the second TSP-like domain of METH2, amino acids 837 to 890 in SEQ ID NO:4; a polypeptide comprising amino acids 280 to 606 in SEQ ID NO:4; a polypeptide comprising amino acids 529 to 548 in SEQ ID NO:4; as well as polypeptides which are at least 95% identical, and more preferably at least 96%, 97%, 98% or 99% identical to the polypeptides described above and also include portions of such polypeptides with at least 30 amino acids and more preferably at least 50 amino acids.

By a polypeptide having an amino acid sequence at least, for example, 95% "identical" to a reference amino acid sequence of a METH1 or METH2 polypeptide is intended that the amino acid sequence of the polypeptide is identical to the reference sequence except that the polypeptide sequence may include up to five amino acid alterations per each 100 amino acids of the reference amino acid of the METH1 or METH2 polypeptide. In other words, to obtain a polypeptide having an amino acid sequence at least 95% identical to a reference amino acid sequence, up to 5% of the amino acid residues in the reference sequence may be deleted or substituted with another amino acid, or a number of amino acids up to 5% of the total amino acid residues in the reference sequence may be inserted into the reference sequence. These alterations of the reference sequence may occur at the amino or carboxy terminal positions of the reference amino acid sequence or anywhere between those terminal positions, interspersed either individually among residues in the reference sequence or in one or more contiguous groups within the reference sequence.

As a practical matter, whether any particular polypeptide is at least 95%, 96%, 97%, 98% or 99% identical to, for instance, the amino acid sequence shown in SEQ ID NO:2 or SEQ ID NO:4 or to the amino acid sequence encoded by deposited cDNA clones can be determined conventionally using known computer programs such the Bestfit program (Wisconsin Sequence Analysis Package, Version 8 for Unix, Genetics Computer Group, University Research Park, 575 Science Drive, Madison, WI 53711). When using Bestfit or any other sequence alignment program to determine whether a particular sequence is, for instance, 95% identical to a reference sequence according to the present invention, the parameters are set, of course, such that the percentage of identity is calculated over the full length of the reference amino acid sequence and that gaps in homology of up to 5% of the total number of amino acid residues in the reference sequence are allowed.

A preferred method for determining the best overall match between a query sequence (a sequence of the present invention) and a subject sequence, also referred to as a global sequence alignment, can be determined using the FASTDB computer program based on the algorithm of Brutlag *et al.*, *Comp. App. Biosci.* 6:237-245 (1990). In a sequence alignment, the query and subject sequences are either both nucleotide sequences or both amino acid sequences. The result of said global sequence alignment is in percent identity. Preferred parameters used in a FASTDB amino acid alignment are: Matrix=PAM 0, k-tuple=2, Mismatch Penalty=1, Joining Penalty=20, Randomization Group Length=0, Cutoff Score=1, Gap Penalty=5, Gap Size Penalty=0.05, Window Size=500 or the length of the subject amino acid sequence, whichever is shorter.

If the subject sequence is shorter than the query sequence due to N- or C-terminal deletions, not because of internal deletions, a manual correction must be made to the results. This is because the FASTDB program does not account for N- and C-terminal truncations of the subject sequence when calculating global percent identity. For subject sequences truncated at the N- and C-termini, relative to the query sequence, the percent identity is corrected by calculating the number

of residues of the query sequence that are N- and C-terminal of the subject sequence, which are not matched/aligned with a corresponding subject residue, as a percent of the total residues of the query sequence. Whether a residue is matched/aligned is determined by the results of the FASTDB sequence alignment.

5 This percentage is then subtracted from the percent identity, calculated by the above FASTDB program using the specified parameters, to arrive at a final percent identity score. This final percent identity score is what is used for the purposes of the present invention. Only residues to the N- and C-termini of the subject sequence, which are not matched/aligned with the query sequence, are
10 considered for the purposes of manually adjusting the percent identity score. That is, only query residue positions outside the farthest N- and C-terminal residues of the subject sequence.

For example, a 90 amino acid residue subject sequence is aligned with a
15 100 residue query sequence to determine percent identity. The deletion occurs at the N-terminus of the subject sequence and therefore, the FASTDB alignment does not show a match/alignment of the first 10 residues at the N-terminus. The 10 unpaired residues represent 10% of the sequence (number of residues at the N- and C-termini not matched/total number of residues in the query sequence) so 10% is subtracted from the percent identity score calculated by the FASTDB
20 program. If the remaining 90 residues were perfectly matched, the final percent identity would be 90%. In another example, a 90 residue subject sequence is compared with a 100 residue query sequence. This time, the deletions are internal, so there are no residues at the N- or C-termini of the subject sequence which are not matched/aligned with the query. In this case, the percent identity calculated
25 by FASTDB is not manually corrected. Once again, only residue positions outside the N- and C-terminal ends of the subject sequence, as displayed in the FASTDB alignment, which are not matched/aligned with the query sequence are manually corrected for. No other manual corrections are made for the purposes of the present invention.

The polypeptides of the present invention are useful as a molecular weight marker on SDS-PAGE gels or on molecular sieve gel filtration columns using methods well known to those of skill in the art.

5 In another aspect, the invention provides a peptide or polypeptide comprising an epitope-bearing portion of a polypeptide of the invention. The epitope of this polypeptide portion is an immunogenic or antigenic epitope of a polypeptide described herein. An "immunogenic epitope" is defined as a part of a protein that elicits an antibody response when the whole protein is the immunogen. On the other hand, a region of a protein molecule to which an
10 antibody can bind is defined as an "antigenic epitope." The number of immunogenic epitopes of a protein generally is less than the number of antigenic epitopes. See, for instance, Geysen *et al.*, *Proc. Natl. Acad. Sci. USA* 81:3998-4002 (1983).

As to the selection of peptides or polypeptides bearing an antigenic epitope
15 (i.e., that contain a region of a protein molecule to which an antibody can bind), it is well known in that art that relatively short synthetic peptides that mimic part of a protein sequence are routinely capable of eliciting an antiserum that reacts with the partially mimicked protein. See, for instance, Sutcliffe, J. G. *et al.*, "Antibodies that react with predetermined sites on proteins", *Science* 219:660-666
20 (1983). Peptides capable of eliciting protein-reactive sera are frequently represented in the primary sequence of a protein, can be characterized by a set of simple chemical rules, and are confined neither to immunodominant regions of intact proteins (i.e., immunogenic epitopes) nor to the amino or carboxyl terminals.

25 Antigenic epitope-bearing peptides and polypeptides of the invention are therefore useful to raise antibodies, including monoclonal antibodies, that bind specifically to a polypeptide of the invention. See, for instance, Wilson *et al.*, *Cell* 37:767-778 (1984) at 777.

30 Antigenic epitope-bearing peptides and polypeptides of the invention preferably contain a sequence of at least seven, more preferably at least nine and

most preferably between about at least about 15 to about 30 amino acids contained within the amino acid sequence of a polypeptide of the invention.

The epitope-bearing peptides and polypeptides of the invention may be produced by any conventional means. Houghten, R. A., "General method for the rapid solid-phase synthesis of large numbers of peptides: specificity of antigen-antibody interaction at the level of individual amino acids", *Proc. Natl. Acad. Sci. USA* 82:5131-5135 (1985). This "Simultaneous Multiple Peptide Synthesis (SMPS)" process is further described in U.S. Patent No. 4,631,211 to Houghten *et al.* (1986).

As one of skill in the art will appreciate, METH1 or METH2 polypeptides of the present invention and the epitope-bearing fragments thereof described above can be combined with parts of the constant domain of immunoglobulins (IgG), resulting in chimeric polypeptides. These fusion proteins facilitate purification and show an increased half-life *in vivo*. This has been shown, e.g., for chimeric proteins consisting of the first two domains of the human CD4-polypeptide and various domains of the constant regions of the heavy or light chains of mammalian immunoglobulins (EPA 394,827; Traunecker *et al.*, *Nature* 331:84-86 (1988)). Fusion proteins that have a disulfide-linked dimeric structure due to the IgG part can also be more efficient in binding and neutralizing other molecules than the monomeric METH1 or METH2 protein or protein fragment alone (Fountoulakis *et al.*, *J. Biochem.* 270:3958-3964 (1995)).

METH1 and METH2 Polynucleotide and Polypeptide Fragments

In the present invention, a "polynucleotide fragment" refers to a short polynucleotide having a nucleic acid sequence contained in the deposited clones or shown in SEQ ID NO:1 or SEQ ID NO:3. The short nucleotide fragments are preferably at least about 15 nt, and more preferably at least about 20 nt, still more preferably at least about 30 nt, and even more preferably, at least about 40 nt in length. A fragment "at least 20 nt in length," for example, is intended to include

20 or more contiguous bases from the cDNA sequence contained in the deposited clones or the nucleotide sequence shown in SEQ ID NO:1 or SEQ ID NO:3. These nucleotide fragments are useful as diagnostic probes and primers as discussed herein. Of course, larger fragments (e.g., 50, 150, 500, 600, 2000 nucleotides) are preferred.

Moreover, representative examples of METH1 or METH2 polynucleotide fragments include, for example, fragments having a sequence from about nucleotide number 1-50, 51-100, 101-150, 151-200, 201-250, 251-300, 301-350, 351-400, 401-450, 451-500, 501-550, 551-600, 651-700, 701-750, 751-800, 800-850, 851-900, 901-950, 951-1000, 1001-1050, 1051-1100, 1101-1150, 1151-1200, 1201-1250, 1251-1300, 1301-1350, 1351-1400, 1401-1450, 1451-1500, 1501-1550, 1551-1600, 1601-1650, 1651-1700, 1701-1750, 1751-1800, 1801-1850, 1851-1900, 1901-1950, 1951-2000, or 2001 to the end of SEQ ID NO:1 or SEQ ID NO:3 or the cDNA contained in the deposited clones. In this context "about" includes the particularly recited ranges, larger or smaller by several (5, 4, 3, 2, or 1) nucleotides, at either terminus or at both termini. Preferably, these fragments encode a polypeptide which has biological activity. More preferably, these polynucleotides can be used as probes or primers as discussed herein.

In the present invention, a "polypeptide fragment" refers to a short amino acid sequence contained in SEQ ID NO:2 or SEQ ID NO:4 or encoded by the cDNA contained in the deposited clones. Protein fragments may be "free-standing," or comprised within a larger polypeptide of which the fragment forms a part or region, most preferably as a single continuous region. Representative examples of polypeptide fragments of the invention, include, for example, fragments from about amino acid number 1-20, 21-40, 41-60, 61-80, 81-100, 102-120, 121-140, 141-160, 161-180, 181-200, 201-220, 221-240, 241-260, 261-280, or 281 to the end of the coding region or SEQ ID NO:2 or SEQ ID NO:4. Moreover, polypeptide fragments can be about 20, 30, 40, 50, 60, 70, 80, 90, 100, 110, 120, 130, 140, or 150 amino acids in length. In this context "about" includes

the particularly recited ranges, larger or smaller by several (5, 4, 3, 2, or 1) amino acids, at either extreme or at both extremes.

Preferred polypeptide fragments include the secreted METH1 or METH2 protein as well as the mature form. Further preferred polypeptide fragments include the secreted METH1 or METH2 protein or the mature form having a continuous series of deleted residues from the amino or the carboxy terminus, or both. For example, any number of amino acids, ranging from 1-60, can be deleted from the amino terminus of either the secreted METH1 or METH2 polypeptide or the mature form. Similarly, any number of amino acids, ranging from 1-30, can be deleted from the carboxy terminus of the secreted METH1 or METH2 protein or mature form. Furthermore, any combination of the above amino and carboxy terminus deletions are preferred. Similarly, polynucleotide fragments encoding these METH1 or METH2 polypeptide fragments are also preferred.

Particularly, N-terminal deletions of the METH1 polypeptide can be described by the general formula m-950, where m is an integer from 2 to 949, where m corresponds to the position of the amino acid residue identified in SEQ ID NO:2. Preferably, N-terminal deletions of the METH1 polypeptide of the invention shown as SEQ ID NO:2 include polypeptides comprising the amino acid sequence of residues: G-2 to S-950; N-3 to S-950; A-4 to S-950; E-5 to S-950; R-6 to S-950; A-7 to S-950; P-8 to S-950; G-9 to S-950; S-10 to S-950; R-11 to S-950; S-12 to S-950; F-13 to S-950; G-14 to S-950; P-15 to S-950; V-16 to S-950; P-17 to S-950; T-18 to S-950; L-19 to S-950; L-20 to S-950; L-21 to S-950; L-22 to S-950; A-23 to S-950; A-24 to S-950; A-25 to S-950; L-26 to S-950; L-27 to S-950; A-28 to S-950; V-29 to S-950; S-30 to S-950; D-31 to S-950; A-32 to S-950; L-33 to S-950; G-34 to S-950; R-35 to S-950; P-36 to S-950; S-37 to S-950; E-38 to S-950; E-39 to S-950; D-40 to S-950; E-41 to S-950; E-42 to S-950; L-43 to S-950; V-44 to S-950; V-45 to S-950; P-46 to S-950; E-47 to S-950; L-48 to S-950; E-49 to S-950; R-50 to S-950; A-51 to S-950; P-52 to S-950; G-53 to S-950; H-54 to S-950; G-55 to S-950; T-56 to S-950; T-57 to S-950; R-58 to S-950; L-59 to S-950; R-60 to S-950; L-61 to S-950; H-62 to S-

Moreover, C-terminal deletions of the METH1 polypeptide can also be described by the general formula 1-n, where n is an integer from 2 to 950, where n corresponds to the position of amino acid residue identified in SEQ ID NO:2.

Preferably, C-terminal deletions of the METH1 polypeptide of the invention shown as SEQ ID NO:2 include polypeptides comprising the amino acid sequence of residues: M-1 to C-949; M-1 to E-948; M-1 to A-947; M-1 to M-946; M-1 to T-945; M-1 to C-944; M-1 to F-943; M-1 to D-942; M-1 to I-941; M-1 to F-940; M-1 to H-939; M-1 to K-938; M-1 to P-937; M-1 to K-936; M-1 to K-935; M-1 to L-934; M-1 to P-933; M-1 to D-932; M-1 to C-931; M-1 to S-930; M-1 to E-929; M-1 to H-928; M-1 to S-927; M-1 to L-926; M-1 to V-925; M-1 to G-924; M-1 to G-923; M-1 to D-922; M-1 to H-921; M-1 to S-920; M-1 to L-919; M-1 to C-918; M-1 to K-917; M-1 to L-916; M-1 to S-915; M-1 to R-914; M-1 to K-913; M-1 to K-912; M-1 to Y-911; M-1 to G-910; M-1 to K-909; M-1 to G-908; M-1 to C-907; M-1 to T-906; M-1 to K-905; M-1 to S-904; M-1 to C-903; M-1 to S-902; M-1 to S-901; M-1 to W-900; M-1 to E-899; M-1 to G-898; M-1 to L-897; M-1 to Q-896; M-1 to W-895; M-1 to Q-894; M-1 to P-893; M-1 to C-892; M-1 to P-891; M-1 to H-890; M-1 to D-889; M-1 to A-888; M-1 to C-887; M-1 to P-886; M-1 to R-885; M-1 to T-884; M-1 to S-883; M-1 to A-882; M-1 to P-881; M-1 to K-880; M-1 to V-879; M-1 to E-878; M-1 to K-877; M-1 to A-876; M-1 to C-875; M-1 to E-874; M-1 to S-873; M-1 to A-872; M-1 to P-871; M-1 to Q-870; M-1 to G-869; M-1 to N-868; M-1 to I-867; M-1 to D-866; M-1 to R-865; M-1 to C-864; M-1 to E-863; M-1 to V-862; M-1 to L-861; M-1 to R-860; M-1 to R-859; M-1 to Q-858; M-1 to W-857; M-1 to G-856; M-1 to L-855; M-1 to E-854; M-1 to C-853; M-1 to S-852; M-1 to K-851; M-1 to S-850; M-1 to C-

to E-47; M-1 to P-46; M-1 to V-45; M-1 to V-44; M-1 to L-43; M-1 to E-42; M-1 to E-41; M-1 to D-40; M-1 to E-39; M-1 to E-38; M-1 to S-37; M-1 to P-36; M-1 to R-35; M-1 to G-34; M-1 to L-33; M-1 to A-32; M-1 to D-31; M-1 to S-30; M-1 to V-29; M-1 to A-28; M-1 to L-27; M-1 to L-26; M-1 to A-25; M-1 to A-24; M-1 to A-23; M-1 to L-22; M-1 to L-21; M-1 to L-20; M-1 to L-19; M-1 to T-18; M-1 to P-17; M-1 to V-16; M-1 to P-15; M-1 to G-14; M-1 to F-13; M-1 to S-12; M-1 to R-11; M-1 to S-10; M-1 to G-9; M-1 to P-8; M-1 to A-7; of SEQ ID NO:2. For example, any of the above listed N- or C-terminal deletions can be combined to produce a N- and C-terminal deleted METH1 polypeptide.

Moreover, N-terminal deletions of the METH2 polypeptide can be described by the general formula m-890, where m is an integer from 2 to 889, where m corresponds to the position of the amino acid residue identified in SEQ ID NO:4. Preferably, N-terminal deletions of the METH2 polypeptide of the invention shown as SEQ ID NO:4 include polypeptides comprising the amino acid sequence of residues: F-2 to L-890; P-3 to L-890; A-4 to L-890; P-5 to L-890; A-6 to L-890; A-7 to L-890; P-8 to L-890; R-9 to L-890; W-10 to L-890; L-11 to L-890; P-12 to L-890; F-13 to L-890; L-14 to L-890; L-15 to L-890; L-16 to L-890; L-17 to L-890; L-18 to L-890; L-19 to L-890; L-20 to L-890; L-21 to L-890; L-22 to L-890; P-23 to L-890; L-24 to L-890; A-25 to L-890; R-26 to L-890; G-27 to L-890; A-28 to L-890; P-29 to L-890; A-30 to L-890; R-31 to L-890; P-32 to L-890; A-33 to L-890; A-34 to L-890; G-35 to L-890; G-36 to L-890; Q-37 to L-890; A-38 to L-890; S-39 to L-890; E-40 to L-890; L-41 to L-890; V-42 to L-890; V-43 to L-890; P-44 to L-890; T-45 to L-890; R-46 to L-890; L-47 to L-890; P-48 to L-890; G-49 to L-890; S-50 to L-890; A-51 to L-890; G-52 to L-890; E-53 to L-890; L-54 to L-890; A-55 to L-890; L-56 to L-890; H-57 to L-890; L-58 to L-890; S-59 to L-890; A-60 to L-890; F-61 to L-890; G-62 to L-890; K-63 to L-890; G-64 to L-890; F-65 to L-890; V-66 to L-890; L-67 to L-890; R-68 to L-890; L-69 to L-890; A-70 to L-890; P-71 to L-890; D-72 to L-890; D-73 to L-890; S-74 to L-890; F-75 to L-890; L-76 to L-890; A-77 to L-890; P-78 to L-890; E-79 to L-890; F-80 to L-890; K-81 to L-

Moreover, C-terminal deletions of the METH2 polypeptide can also be
 described by the general formula 1-n, where n is an integer from 2 to 890 where
 n corresponds to the position of amino acid residue identified in SEQ ID NO:4.
 Preferably, C-terminal deletions of the METH2 polypeptide of the invention
 25 shown as SEQ ID NO:4 include polypeptides comprising the amino acid sequence
 of residues: M-1 to P-889; M-1 to C-888; M-1 to L-887; M-1 to Q-886; M-1 to

to G-545; M-1 to G-544; M-1 to C-543; M-1 to T-542; M-1 to R-541; M-1 to S-540; M-1 to C-539; M-1 to E-538; M-1 to G-537; M-1 to W-536; M-1 to P-535; M-1 to G-534; M-1 to W-533; M-1 to P-532; M-1 to A-531; M-1 to W-530; M-1 to G-529; M-1 to G-528; M-1 to D-527; M-1 to V-526; M-1 to V-525; M-1 to P-524; M-1 to K-523; M-1 to P-522; M-1 to R-521; M-1 to E-520; M-1 to V-519; M-1 to E-518; M-1 to E-517; M-1 to E-516; M-1 to P-515; M-1 to L-514; M-1 to C-513; M-1 to S-512; M-1 to G-511; M-1 to E-510; M-1 to S-509; M-1 to C-508; M-1 to L-507; M-1 to H-506; M-1 to G-505; M-1 to P-504; M-1 to G-503; M-1 to C-502; M-1 to P-501; M-1 to T-500; M-1 to G-499; M-1 to D-498; M-1 to A-497; M-1 to W-496; M-1 to P-495; M-1 to L-494; M-1 to S-493; M-1 to G-492; M-1 to N-491; M-1 to K-490; M-1 to T-489; M-1 to H-488; M-1 to C-487; M-1 to L-486; M-1 to P-485; M-1 to E-484; M-1 to A-483; M-1 to G-482; M-1 to D-481; M-1 to T-480; M-1 to H-479; M-1 to C-478; M-1 to W-477; M-1 to L-476; M-1 to Q-475; M-1 to A-474; M-1 to C-473; M-1 to V-472; M-1 to D-471; M-1 to Q-470; M-1 to A-469; M-1 to S-468; M-1 to T-467; M-1 to N-466; M-1 to P-465; M-1 to C-464; M-1 to H-463; M-1 to R-462; M-1 to F-461; M-1 to D-460; M-1 to P-459; M-1 to G-458; M-1 to F-457; M-1 to I-456; M-1 to Q-455; M-1 to R-454; M-1 to C-453; M-1 to Q-452; M-1 to Q-451; M-1 to D-450; M-1 to L-449; M-1 to Q-448; M-1 to Y-447; M-1 to L-446; M-1 to A-445; M-1 to M-444; M-1 to R-443; M-1 to G-442; M-1 to P-441; M-1 to L-440; M-1 to G-439; M-1 to T-438; M-1 to P-437; M-1 to L-436; M-1 to P-435; M-1 to L-434; M-1 to A-433; M-1 to A-432; M-1 to G-431; M-1 to P-430; M-1 to A-429; M-1 to D-428; M-1 to L-427; M-1 to L-426; M-1 to C-425; M-1 to D-424; M-1 to G-423; M-1 to H-422; M-1 to G-421; M-1 to G-420; M-1 to D-419; M-1 to L-418; M-1 to L-417; M-1 to E-416; M-1 to T-415; M-1 to L-414; M-1 to Y-413; M-1 to M-412; M-1 to A-411; M-1 to S-410; M-1 to C-409; M-1 to P-408; M-1 to S-407; M-1 to W-406; M-1 to P-405; M-1 to L-404; M-1 to T-403; M-1 to Q-402; M-1 to N-401; M-1 to L-400; M-1 to H-399; M-1 to V-398; M-1 to F-397; M-1 to L-396; M-1 to P-395; M-1 to A-394; M-1 to M-393; M-1 to V-392; M-1 to H-391; M-1 to H-390; M-1 to K-389; M-1 to G-388; M-1 to M-387;

M-1 to P-386; M-1 to G-385; M-1 to F-384; M-1 to L-383; M-1 to R-382; M-1 to T-381; M-1 to C-380; M-1 to P-379; M-1 to K-378; M-1 to S-377; M-1 to D-376; M-1 to D-375; M-1 to H-374; M-1 to P-373; M-1 to M-372; M-1 to S-371; M-1 to L-370; M-1 to V-369; M-1 to H-368; M-1 to G-367; M-1 to L-366; M-1 to E-365; M-1 to H-364; M-1 to A-363; M-1 to L-362; M-1 to T-361; M-1 to H-360; M-1 to A-359; M-1 to A-358; M-1 to Q-357; M-1 to L-356; M-1 to G-355; M-1 to E-354; M-1 to D-353; M-1 to E-352; M-1 to I-351; M-1 to V-350; M-1 to S-349; M-1 to C-348; M-1 to S-347; M-1 to K-346; M-1 to N-345; M-1 to P-344; M-1 to D-343; M-1 to C-342; M-1 to I-341; M-1 to T-340; M-1 to G-339; M-1 to I-338; M-1 to D-337; M-1 to A-336; M-1 to V-335; M-1 to G-334; M-1 to L-333; M-1 to T-332; M-1 to D-331; M-1 to C-330; M-1 to L-329; M-1 to G-328; M-1 to E-327; M-1 to Q-326; M-1 to G-325; M-1 to C-324; M-1 to F-323; M-1 to N-322; M-1 to Q-321; M-1 to R-320; M-1 to T-319; M-1 to L-318; M-1 to L-317; M-1 to I-316; M-1 to A-315; M-1 to T-314; M-1 to D-313; M-1 to Y-312; M-1 to H-311; M-1 to E-310; M-1 to P-309; M-1 to H-308; M-1 to R-307; M-1 to D-306; M-1 to S-305; M-1 to P-304; M-1 to Q-303; M-1 to N-302; M-1 to F-301; M-1 to R-300; M-1 to R-299; M-1 to Q-298; M-1 to W-297; M-1 to N-296; M-1 to C-295; M-1 to F-294; M-1 to N-293; M-1 to R-292; M-1 to L-291; M-1 to T-290; M-1 to L-289; M-1 to G-288; M-1 to G-287; M-1 to N-286; M-1 to D-285; M-1 to S-284; M-1 to V-283; M-1 to E-282; M-1 to P-281; M-1 to G-280; M-1 to W-279; M-1 to K-278; M-1 to E-277; M-1 to D-276; M-1 to E-275; M-1 to V-274; M-1 to I-273; M-1 to L-272; M-1 to V-271; M-1 to K-270; M-1 to V-269; M-1 to V-268; M-1 to M-267; M-1 to L-266; M-1 to N-265; M-1 to I-264; M-1 to S-263; M-1 to N-262; M-1 to K-261; M-1 to I-260; M-1 to S-259; M-1 to P-258; M-1 to H-257; M-1 to K-256; M-1 to Y-255; M-1 to I-254; M-1 to R-253; M-1 to A-252; M-1 to A-251; M-1 to V-250; M-1 to S-249; M-1 to M-248; M-1 to L-247; M-1 to T-246; M-1 to L-245; M-1 to I-244; M-1 to H-243; M-1 to N-242; M-1 to Q-241; M-1 to L-240; M-1 to D-239; M-1 to A-238; M-1 to G-237; M-1 to Y-236; M-1 to F-235; M-1 to A-234; M-1 to A-233; M-1 to M-232; M-1 to S-231; M-1 to A-230; M-1 to D-229; M-1 to A-228;

M-1 to V-227; M-1 to L-226; M-1 to L-225; M-1 to T-224; M-1 to E-223; M-1 to V-222; M-1 to F-221; M-1 to R-220; M-1 to A-219; M-1 to E-218; M-1 to S-217; M-1 to V-216; M-1 to F-215; M-1 to R-214; M-1 to K-213; M-1 to T-212; M-1 to R-211; M-1 to S-210; M-1 to T-209; M-1 to A-208; M-1 to G-207; M-1 to L-206; M-1 to P-205; M-1 to P-204; M-1 to P-203; M-1 to P-202; M-1 to E-201; M-1 to S-200; M-1 to A-199; M-1 to G-198; M-1 to E-197; M-1 to A-196; M-1 to E-195; M-1 to E-194; M-1 to E-193; M-1 to Q-192; M-1 to S-191; M-1 to E-190; M-1 to E-189; M-1 to E-188; M-1 to S-187; M-1 to D-186; M-1 to E-185; M-1 to Q-184; M-1 to H-183; M-1 to D-182; M-1 to G-181; M-1 to R-180; M-1 to E-179; M-1 to Q-178; M-1 to R-177; M-1 to Q-176; M-1 to G-175; M-1 to E-174; M-1 to G-173; M-1 to T-172; M-1 to E-171; M-1 to V-170; M-1 to E-169; M-1 to W-168; M-1 to E-167; M-1 to P-166; M-1 to G-165; M-1 to R-164; M-1 to P-163; M-1 to L-162; M-1 to P-161; M-1 to R-160; M-1 to A-159; M-1 to G-158; M-1 to A-157; M-1 to P-156; M-1 to G-155; M-1 to W-154; M-1 to R-153; M-1 to Q-152; M-1 to L-151; M-1 to R-150; M-1 to H-149; M-1 to P-148; M-1 to Q-147; M-1 to A-146; M-1 to L-145; M-1 to S-144; M-1 to G-143; M-1 to G-142; M-1 to A-141; M-1 to G-140; M-1 to Q-139; M-1 to P-138; M-1 to Q-137; M-1 to I-136; M-1 to T-135; M-1 to F-134; M-1 to E-133; M-1 to E-132; M-1 to G-131; M-1 to D-130; M-1 to L-129; M-1 to L-128; M-1 to F-127; M-1 to S-126; M-1 to G-125; M-1 to S-124; M-1 to L-123; M-1 to G-122; M-1 to R-121; M-1 to C-120; M-1 to L-119; M-1 to S-118; M-1 to V-117; M-1 to A-116; M-1 to A-115; M-1 to L-114; M-1 to S-113; M-1 to E-112; M-1 to P-111; M-1 to E-110; M-1 to G-109; M-1 to N-108; M-1 to V-107; M-1 to T-106; M-1 to G-105; M-1 to S-104; M-1 to F-103; M-1 to F-102; M-1 to C-101; M-1 to G-100; M-1 to R-99; M-1 to L-98; M-1 to G-97; M-1 to R-96; M-1 to E-95; M-1 to G-94; M-1 to G-93; M-1 to T-92; M-1 to A-91; M-1 to R-90; M-1 to G-89; M-1 to S-88; M-1 to G-87; M-1 to G-86; M-1 to L-85; M-1 to R-84; M-1 to E-83; M-1 to I-82; M-1 to K-81; M-1 to F-80; M-1 to E-79; M-1 to P-78; M-1 to A-77; M-1 to L-76; M-1 to F-75; M-1 to S-74; M-1 to D-73; M-1 to D-72; M-1 to P-71; M-1 to A-70; M-1 to L-69; M-1 to R-68; M-1 to L-67; M-1 to V-66; M-

1 to F-65; M-1 to G-64; M-1 to K-63; M-1 to G-62; M-1 to F-61; M-1 to A-60; M-1 to S-59; M-1 to L-58; M-1 to H-57; M-1 to L-56; M-1 to A-55; M-1 to L-54; M-1 to E-53; M-1 to G-52; M-1 to A-51; M-1 to S-50; M-1 to G-49; M-1 to P-48; M-1 to L-47; M-1 to R-46; M-1 to T-45; M-1 to P-44; M-1 to V-43; M-1 to V-42; M-1 to L-41; M-1 to E-40; M-1 to S-39; M-1 to A-38; M-1 to Q-37; M-1 to G-36; M-1 to G-35; M-1 to A-34; M-1 to A-33; M-1 to P-32; M-1 to R-31; M-1 to A-30; M-1 to P-29; M-1 to A-28; M-1 to G-27; M-1 to R-26; M-1 to A-25; M-1 to L-24; M-1 to P-23; M-1 to L-22; M-1 to L-21; M-1 to L-20; M-1 to L-19; M-1 to L-18; M-1 to L-17; M-1 to L-16; M-1 to L-15; M-1 to L-14; M-1 to F-13; M-1 to P-12; M-1 to L-11; M-1 to W-10; M-1 to R-9; M-1 to P-8; M-1 to A-7; of SEQ ID NO:4. Preferably, any of the above listed N- or C-terminal deletions can be combined to produce a N- and C-terminal deleted METH2 polypeptide.

The invention also provides polypeptides having one or more amino acids deleted from both the amino and the carboxyl termini, which may be described generally as having residues m-n of SEQ ID NO:2 or SEQ ID NO:4, where n and m are integers as described above.

Also preferred are METH1 or METH2 polypeptide and polynucleotide fragments characterized by structural or functional domains. Preferred embodiments of the invention include fragments that comprise alpha-helix and alpha-helix forming regions ("alpha-regions"), beta-sheet and beta-sheet-forming regions ("beta-regions"), turn and turn-forming regions ("turn-regions"), coil and coil-forming regions ("coil-regions"), hydrophilic regions, hydrophobic regions, alpha amphipathic regions, beta amphipathic regions, flexible regions, surface-forming regions, substrate binding region, and high antigenic index regions. As set out in the Figures, such preferred regions include Garnier-Robson alpha-regions, beta-regions, turn-regions, and coil-regions, Chou-Fasman alpha-regions, beta-regions, and turn-regions, Kyte-Doolittle hydrophilic regions and hydrophobic regions, Eisenberg alpha and beta amphipathic regions, Karplus-Schulz flexible regions, Emini surface-forming regions, and Jameson-Wolf high

antigenic index regions. Polypeptide fragments of SEQ ID NO:2 falling within conserved domains are specifically contemplated by the present invention. (See Figures 10 & 11 and Tables 1 & 2.) Moreover, polynucleotide fragments encoding these domains are also contemplated.

5 Other preferred fragments are biologically active METH1 or METH2 fragments. Biologically active fragments are those exhibiting activity similar, but not necessarily identical, to an activity of the METH1 or METH2 polypeptide. The biological activity of the fragments may include an improved desired activity, or a decreased undesirable activity.

10 However, many polynucleotide sequences, such as EST sequences, are publicly available and accessible through sequence databases. Some of these sequences are related to SEQ ID NO:1 or SEQ ID NO:3 and may have been publicly available prior to conception of the present invention. Preferably, such related polynucleotides are specifically excluded from the scope of the present
15 invention. To list every related sequence would be cumbersome. Accordingly, preferably excluded from the present invention are one or more polynucleotides comprising a nucleotide sequence described by the general formula of a-b, where a is any integer between 1 to 936 of SEQ ID NO:1, b is an integer of 15 to 950, where both a and b correspond to the positions of nucleotide residues shown in
20 SEQ ID NO:1, and where the b is greater than or equal to a + 14. Moreover, preferably excluded from the present invention are one or more polynucleotides comprising a nucleotide sequence described by the general formula of a-b, where a is any integer between 1 to 876 of SEQ ID NO:3, b is an integer of 15 to 890, where both a and b correspond to the positions of nucleotide residues shown in
25 SEQ ID NO:3, and where the b is greater than or equal to a + 14.

Epitopes & Antibodies

In the present invention, "epitopes" refer to METH1 or METH2 polypeptide fragments having antigenic or immunogenic activity in an animal, especially in a human. A preferred embodiment of the present invention relates

to a METH1 or METH2 polypeptide fragment comprising an epitope, as well as the polynucleotide encoding this fragment. A region of a protein molecule to which an antibody can bind is defined as an "antigenic epitope." In contrast, an "immunogenic epitope" is defined as a part of a protein that elicits an antibody response. (See, for instance, Geysen *et al.*, *Proc. Natl. Acad. Sci. USA* 81:3998-4002 (1983).)

Fragments which function as epitopes may be produced by any conventional means. (See, e.g., Houghten, R. A., *Proc. Natl. Acad. Sci. USA* 82:5131-5135 (1985) further described in U.S. Patent No. 4,631,211.)

In the present invention, antigenic epitopes preferably contain a sequence of at least seven, more preferably at least nine, and most preferably between about 15 to about 30 amino acids. Antigenic epitopes are useful to raise antibodies, including monoclonal antibodies, that specifically bind the epitope. (See, for instance, Wilson *et al.*, *Cell* 37:767-778 (1984); Sutcliffe, J. G. *et al.*, *Science* 219:660-666 (1983).)

Similarly, immunogenic epitopes can be used to induce antibodies according to methods well known in the art. (See, for instance, Sutcliffe *et al.*, *supra*; Wilson *et al.*, *supra*; Chow, M. *et al.*, *Proc. Natl. Acad. Sci. USA* 82:910-914; and Bittle, F. J. *et al.*, *J. Gen. Virol.* 66:2347-2354 (1985).) A preferred immunogenic epitope includes the secreted protein. The immunogenic epitopes may be presented together with a carrier protein, such as an albumin, to an animal system (such as rabbit or mouse) or, if it is long enough (at least about 25 amino acids), without a carrier. However, immunogenic epitopes comprising as few as 8 to 10 amino acids have been shown to be sufficient to raise antibodies capable of binding to, at the very least, linear epitopes in a denatured polypeptide (e.g., in Western blotting.)

Using DNASTar analysis, SEQ ID NO:2 was found antigenic at amino acids: 2-14, 32-44, 47-60, 66-78, 87-103, 109-118, 146-162, 168-180, 183-219, 223-243, 275-284, 296-306, 314-334, 341-354, 357-376, 392-399, 401-410, 418-429, 438-454, 456-471, 474-488, 510-522, 524-538, 550-561, 565-626, 630-643,

659-671, 679-721, 734-749, 784-804, 813-820, 825-832, 845-854, 860-894, 899-917, 919-924 and 928-939. Thus, these regions could be used as epitopes to produce antibodies against the protein encoded by METH1 cDNA.

Using DNASTar analysis, SEQ ID NO:4 was found antigenic at amino acids: 26-38, 45-52, 69-76, 80-99, 105-113, 129-136, 138-217, 254-263, 273-289, 294-313, 321-331, 339-356, 371-383, 417-427, 438-443, 459-471, 479-505, 507-526, 535-546, 550-607, 615-640, 648-653, 660-667, 669-681, 683-704, 717-732, 737-743, 775-787, 797-804, 811-825, 840-867 and 870-884. Thus, these regions could be used as epitopes to produce antibodies against the protein encoded by METH2 cDNA.

As used herein, the term "antibody" (Ab) or "monoclonal antibody" (Mab) is meant to include intact molecules as well as antibody fragments (such as, for example, Fab and F(ab')₂ fragments) which are capable of specifically binding to protein. Fab and F(ab')₂ fragments lack the Fc fragment of intact antibody, clear more rapidly from the circulation, and may have less non-specific tissue binding than an intact antibody. (Wahl *et al.*, *J. Nucl. Med.* 24:316-325 (1983).) Thus, these fragments are preferred, as well as the products of a FAB or other immunoglobulin expression library. Moreover, antibodies of the present invention include chimeric, single chain, and humanized antibodies.

Fusion Proteins

Any METH1 or METH2 polypeptide can be used to generate fusion proteins. For example, the METH1 or METH2 polypeptide, when fused to a second protein, can be used as an antigenic tag. Antibodies raised against the METH1 or METH2 polypeptide can be used to indirectly detect the second protein by binding to the METH1 or METH2. Moreover, because secreted proteins target cellular locations based on trafficking signals, the METH1 or METH2 polypeptides can be used as a targeting molecule once fused to other proteins.

Examples of domains that can be fused to METH1 or METH2 polypeptides include not only heterologous signal sequences, but also other heterologous functional regions. The fusion does not necessarily need to be direct, but may occur through linker sequences.

Moreover, fusion proteins may also be engineered to improve characteristics of the METH1 or METH2 polypeptide. For instance, a region of additional amino acids, particularly charged amino acids, may be added to the N-terminus of the METH1 or METH2 polypeptide to improve stability and persistence during purification from the host cell or subsequent handling and storage. Also, peptide moieties may be added to the METH1 or METH2 polypeptide to facilitate purification. Such regions may be removed prior to final preparation of the METH1 or METH2 polypeptide. The addition of peptide moieties to facilitate handling of polypeptides are familiar and routine techniques in the art.

Moreover, METH1 or METH2 polypeptides, including fragments, and specifically epitopes, can be combined with parts of the constant domain of immunoglobulins (IgG), resulting in chimeric polypeptides. These fusion proteins facilitate purification and show an increased half-life in vivo. One reported example describes chimeric proteins consisting of the first two domains of the human CD4-polypeptide and various domains of the constant regions of the heavy or light chains of mammalian immunoglobulins. (EP A 394,827; Traunecker *et al.*, *Nature* 331:84-86 (1988).) Fusion proteins having disulfide-linked dimeric structures (due to the IgG) can also be more efficient in binding and neutralizing other molecules, than the monomeric secreted protein or protein fragment alone. (Fountoulakis *et al.*, *J. Biochem.* 270:3958-3964 (1995).)

Similarly, EP-A-O 464 533 (Canadian counterpart 2045869) discloses fusion proteins comprising various portions of constant region of immunoglobulin molecules together with another human protein or part thereof. In many cases, the Fc part in a fusion protein is beneficial in therapy and diagnosis, and thus can result in, for example, improved pharmacokinetic properties. (EP-A 0232 262.)

Alternatively, deleting the Fc part after the fusion protein has been expressed, detected, and purified, would be desired. For example, the Fc portion may hinder therapy and diagnosis if the fusion protein is used as an antigen for immunizations. In drug discovery, for example, human proteins, such as hIL-5, have been fused with Fc portions for the purpose of high-throughput screening assays to identify antagonists of hIL-5. (See, D. Bennett et al., J. Molecular Recognition 8:52-58 (1995); K. Johanson et al., J. Biol. Chem. 270:9459-9471 (1995).)

Moreover, the METH1 or METH2 polypeptides can be fused to marker sequences, such as a peptide which facilitates purification of METH1 or METH2. In preferred embodiments, the marker amino acid sequence is a hexa-histidine peptide, such as the tag provided in a pQE vector (QIAGEN, Inc., 9259 Eton Avenue, Chatsworth, CA, 91311), among others, many of which are commercially available. As described in Gentz *et al.*, *Proc. Natl. Acad. Sci. USA* 86:821-824 (1989), for instance, hexa-histidine provides for convenient purification of the fusion protein. Another peptide tag useful for purification, the "HA" tag, corresponds to an epitope derived from the influenza hemagglutinin protein. (Wilson et al., *Cell* 37:767 (1984).)

Thus, any of these above fusions can be engineered using the METH1 or METH2 polynucleotides or the polypeptides.

Biological Activities of METH1 or METH2

METH1 or METH2 polynucleotides and polypeptides can be used in assays to test for one or more biological activities. If METH1 or METH2 polynucleotides and polypeptides do exhibit activity in a particular assay, it is likely that METH1 or METH2 may be involved in the diseases associated with the biological activity. Therefore, METH1 or METH2 could be used to treat the associated disease.

Immune Activity

METH1 or METH2 polypeptides or polynucleotides may be useful in treating deficiencies or disorders of the immune system, by activating or inhibiting the proliferation, differentiation, or mobilization (chemotaxis) of immune cells.

5 Immune cells develop through a process called hematopoiesis, producing myeloid (platelets, red blood cells, neutrophils, and macrophages) and lymphoid (B and T lymphocytes) cells from pluripotent stem cells. The etiology of these immune deficiencies or disorders may be genetic, somatic, such as cancer or some autoimmune disorders, acquired (e.g., by chemotherapy or toxins), or infectious.

10 Moreover, METH1 or METH2 polynucleotides or polypeptides can be used as a marker or detector of a particular immune system disease or disorder.

METH1 or METH2 polynucleotides or polypeptides may be useful in treating or detecting deficiencies or disorders of hematopoietic cells. METH1 or METH2 polypeptides or polynucleotides could be used to increase differentiation and proliferation of hematopoietic cells, including the pluripotent stem cells, in an effort to treat those disorders associated with a decrease in certain (or many) types hematopoietic cells. Examples of immunologic deficiency syndromes include, but are not limited to: blood protein disorders (e.g. agammaglobulinemia, dysgammaglobulinemia), ataxia telangiectasia, common variable
15 immunodeficiency, Digeorge Syndrome, HIV infection, HTLV-BLV infection, leukocyte adhesion deficiency syndrome, lymphopenia, phagocyte bactericidal dysfunction, severe combined immunodeficiency (SCIDs), Wiskott-Aldrich Disorder, anemia, thrombocytopenia, or hemoglobinuria.

Moreover, METH1 or METH2 polypeptides or polynucleotides can also
25 be used to modulate hemostatic (the stopping of bleeding) or thrombolytic activity (clot formation). For example, by increasing hemostatic or thrombolytic activity, METH1 or METH2 polynucleotides or polypeptides could be used to treat blood coagulation disorders (e.g., afibrinogenemia, factor deficiencies), blood platelet disorders (e.g. thrombocytopenia), or wounds resulting from trauma, surgery, or
30 other causes. Alternatively, METH1 or METH2 polynucleotides or polypeptides

that can decrease hemostatic or thrombolytic activity could be used to inhibit or dissolve clotting, important in the treatment of heart attacks (infarction), strokes, or scarring.

METH1 or METH2 polynucleotides or polypeptides may also be useful in treating or detecting autoimmune disorders. Many autoimmune disorders result from inappropriate recognition of self as foreign material by immune cells. This inappropriate recognition results in an immune response leading to the destruction of the host tissue. Therefore, the administration of METH1 or METH2 polypeptides or polynucleotides that can inhibit an immune response, particularly the proliferation, differentiation, or chemotaxis of T-cells, may be an effective therapy in preventing autoimmune disorders.

Examples of autoimmune disorders that can be treated or detected by METH1 or METH2 include, but are not limited to: Addison's Disease, hemolytic anemia, antiphospholipid syndrome, rheumatoid arthritis, dermatitis, allergic encephalomyelitis, glomerulonephritis, Goodpasture's Syndrome, Graves' Disease, Multiple Sclerosis, Myasthenia Gravis, Neuritis, Ophthalmia, Bullous Pemphigoid, Pemphigus, Polyendocrinopathies, Purpura, Reiter's Disease, Stiff-Man Syndrome, Autoimmune Thyroiditis, Systemic Lupus Erythematosus, Autoimmune Pulmonary Inflammation, Guillain-Barre Syndrome, insulin dependent diabetes mellitis, and autoimmune inflammatory eye disease.

Similarly, allergic reactions and conditions, such as asthma (particularly allergic asthma) or other respiratory problems, may also be treated by METH1 or METH2 polypeptides or polynucleotides. Moreover, METH1 or METH2 can be used to treat anaphylaxis, hypersensitivity to an antigenic molecule, or blood group incompatibility.

METH1 or METH2 polynucleotides or polypeptides may also be used to treat and/or prevent organ rejection or graft-versus-host disease (GVHD). Organ rejection occurs by host immune cell destruction of the transplanted tissue through an immune response. Similarly, an immune response is also involved in GVHD, but, in this case, the foreign transplanted immune cells destroy the host tissues.

The administration of METH1 or METH2 polypeptides or polynucleotides that inhibits an immune response, particularly the proliferation, differentiation, or chemotaxis of T-cells, may be an effective therapy in preventing organ rejection or GVHD.

5 Similarly, METH1 or METH2 polypeptides or polynucleotides may also be used to modulate inflammation. For example, METH1 or METH2 polypeptides or polynucleotides may inhibit the proliferation and differentiation of cells involved in an inflammatory response. These molecules can be used to treat inflammatory conditions, both chronic and acute conditions, including
10 inflammation associated with infection (e.g., septic shock, sepsis, or systemic inflammatory response syndrome (SIRS)), ischemia-reperfusion injury, endotoxin lethality, arthritis, complement-mediated hyperacute rejection, nephritis, cytokine or chemokine induced lung injury, inflammatory bowel disease, Crohn's disease, or resulting from over production of cytokines (e.g., TNF or IL-1.)

15 *Hyperproliferative Disorders*

METH1 or METH2 polypeptides or polynucleotides can be used to treat or detect hyperproliferative disorders, including neoplasms. METH1 or METH2 polypeptides or polynucleotides may inhibit the proliferation of the disorder through direct or indirect interactions. Alternatively, METH1 or METH2
20 polypeptides or polynucleotides may proliferate other cells which can inhibit the hyperproliferative disorder.

For example, by increasing an immune response, particularly increasing antigenic qualities of the hyperproliferative disorder or by proliferating, differentiating, or mobilizing T-cells, hyperproliferative disorders can be treated.
25 This immune response may be increased by either enhancing an existing immune response, or by initiating a new immune response. Alternatively, decreasing an immune response may also be a method of treating hyperproliferative disorders, such as a chemotherapeutic agent.

Examples of hyperproliferative disorders that can be treated or detected by METH1 or METH2 polynucleotides or polypeptides include, but are not limited to neoplasms located in the: abdomen, bone, breast, digestive system, liver, pancreas, peritoneum, endocrine glands (adrenal, parathyroid, pituitary, testicles, ovary, thymus, thyroid), eye, head and neck, nervous (central and peripheral), lymphatic system, pelvic, skin, soft tissue, spleen, thoracic, and urogenital.

Similarly, other hyperproliferative disorders can also be treated or detected by METH1 or METH2 polynucleotides or polypeptides. Examples of such hyperproliferative disorders include, but are not limited to: hypergammaglobulinemia, lymphoproliferative disorders, paraproteinemias, purpura, sarcoidosis, Sezary Syndrome, Waldenström's Macroglobulinemia, Gaucher's Disease, histiocytosis, and any other hyperproliferative disease, besides neoplasia, located in an organ system listed above.

Infectious Disease

METH1 or METH2 polypeptides or polynucleotides can be used to treat or detect infectious agents. For example, by increasing the immune response, particularly increasing the proliferation and differentiation of B and/or T cells, infectious diseases may be treated. The immune response may be increased by either enhancing an existing immune response, or by initiating a new immune response. Alternatively, METH1 or METH2 polypeptides or polynucleotides may also directly inhibit the infectious agent, without necessarily eliciting an immune response.

Viruses are one example of an infectious agent that can cause disease or symptoms that can be treated or detected by METH1 or METH2 polynucleotides or polypeptides. Examples of viruses, include, but are not limited to the following DNA and RNA viral families: Arbovirus, Adenoviridae, Arenaviridae, Arterivirus, Birnaviridae, Bunyaviridae, Caliciviridae, Circoviridae, Coronaviridae, Flaviviridae, Hepadnaviridae (Hepatitis), Herpesviridae (such as, Cytomegalovirus, Herpes Simplex, Herpes Zoster), Mononegavirus (e.g.,

Paramyxoviridae, Morbillivirus, Rhabdoviridae), Orthomyxoviridae (e.g., Influenza), Papovaviridae, Parvoviridae, Picornaviridae, Poxviridae (such as Smallpox or Vaccinia), Reoviridae (e.g., Rotavirus), Retroviridae (HTLV-I, HTLV-II, Lentivirus), and Togaviridae (e.g., Rubivirus). Viruses falling within
5 these families can cause a variety of diseases or symptoms, including, but not limited to: arthritis, bronchiollitis, encephalitis, eye infections (e.g., conjunctivitis, keratitis), chronic fatigue syndrome, hepatitis (A, B, C, E, Chronic Active, Delta), meningitis, opportunistic infections (e.g., AIDS), pneumonia, Burkitt's Lymphoma, chickenpox, hemorrhagic fever, Measles, Mumps, Parainfluenza,
10 Rabies, the common cold, Polio, leukemia, Rubella, sexually transmitted diseases, skin diseases (e.g., Kaposi's, warts), and viremia. METH1 or METH2 polypeptides or polynucleotides can be used to treat or detect any of these symptoms or diseases.

Similarly, bacterial or fungal agents that can cause disease or symptoms
15 and that can be treated or detected by METH1 or METH2 polynucleotides or polypeptides include, but not limited to, the following Gram-Negative and Gram-positive bacterial families and fungi: Actinomycetales (e.g., Corynebacterium, Mycobacterium, Norcardia), Aspergillosis, Bacillaceae (e.g., Anthrax, Clostridium), Bacteroidaceae, Blastomycosis, Bordetella, Borrelia, Brucellosis,
20 Candidiasis, Campylobacter, Coccidioidomycosis, Cryptococcosis, Dermatocycoses, Enterobacteriaceae (Klebsiella, Salmonella, Serratia, Yersinia), Erysipelothrix, Helicobacter, Legionellosis, Leptospirosis, Listeria, Mycoplasmatales, Neisseriaceae (e.g., Acinetobacter, Gonorrhea, Meningococcal), Pasteurellaceae Infections (e.g., Actinobacillus, Haemophilus, Pasteurella),
25 Pseudomonas, Rickettsiaceae, Chlamydiaceae, Syphilis, and Staphylococcal. These bacterial or fungal families can cause the following diseases or symptoms, including, but not limited to: bacteremia, endocarditis, eye infections (conjunctivitis, tuberculosis, uveitis), gingivitis, opportunistic infections (e.g., AIDS related infections), paronychia, prosthesis-related infections, Reiter's
30 Disease, respiratory tract infections, such as Whooping Cough or Empyema,

sepsis, Lyme Disease, Cat-Scratch Disease, Dysentery, Paratyphoid Fever, food poisoning, Typhoid, pneumonia, Gonorrhea, meningitis, Chlamydia, Syphilis, Diphtheria, Leprosy, Paratuberculosis, Tuberculosis, Lupus, Botulism, gangrene, tetanus, impetigo, Rheumatic Fever, Scarlet Fever, sexually transmitted diseases, skin diseases (e.g., cellulitis, dermatocycoses), toxemia, urinary tract infections, wound infections. METH1 or METH2 polypeptides or polynucleotides can be used to treat or detect any of these symptoms or diseases.

Moreover, parasitic agents causing disease or symptoms that can be treated or detected by METH1 or METH2 polynucleotides or polypeptides include, but not limited to, the following families: Amebiasis, Babesiosis, Coccidiosis, Cryptosporidiosis, Dientamoebiasis, Dourine, Ectoparasitic, Giardiasis, Helminthiasis, Leishmaniasis, Theileriasis, Toxoplasmosis, Trypanosomiasis, and Trichomonas. These parasites can cause a variety of diseases or symptoms, including, but not limited to: Scabies, Trombiculiasis, eye infections, intestinal disease (e.g., dysentery, giardiasis), liver disease, lung disease, opportunistic infections (e.g., AIDS related), Malaria, pregnancy complications, and toxoplasmosis. METH1 or METH2 polypeptides or polynucleotides can be used to treat or detect any of these symptoms or diseases.

Preferably, treatment using METH1 or METH2 polypeptides or polynucleotides could either be by administering an effective amount of METH1 or METH2 polypeptide to the patient, or by removing cells from the patient, supplying the cells with METH1 or METH2 polynucleotide, and returning the engineered cells to the patient (*ex vivo* therapy). Moreover, the METH1 or METH2 polypeptide or polynucleotide can be used as an antigen in a vaccine to raise an immune response against infectious disease.

Regeneration

METH1 or METH2 polynucleotides or polypeptides can be used to differentiate, proliferate, and attract cells, leading to the regeneration of tissues. (See, *Science* 276:59-87 (1997).) The regeneration of tissues could be used to

repair, replace, or protect tissue damaged by congenital defects, trauma (wounds, burns, incisions, or ulcers), age, disease (e.g. osteoporosis, osteoarthritis, periodontal disease, liver failure), surgery, including cosmetic plastic surgery, fibrosis, reperfusion injury, or systemic cytokine damage.

5 Tissues that could be regenerated using the present invention include organs (e.g., pancreas, liver, intestine, kidney, skin, endothelium), muscle (smooth, skeletal or cardiac), vascular (including vascular endothelium), nervous, hematopoietic, and skeletal (bone, cartilage, tendon, and ligament) tissue. Preferably, regeneration occurs without or decreased scarring. Regeneration also
10 may include angiogenesis.

 Moreover, METH1 or METH2 polynucleotides or polypeptides may increase regeneration of tissues difficult to heal. For example, increased tendon/ligament regeneration would quicken recovery time after damage. METH1
15 or METH2 polynucleotides or polypeptides of the present invention could also be used prophylactically in an effort to avoid damage. Specific diseases that could be treated include of tendinitis, carpal tunnel syndrome, and other tendon or ligament defects. A further example of tissue regeneration of non-healing wounds includes pressure ulcers, ulcers associated with vascular insufficiency, surgical, and traumatic wounds.

20 Similarly, nerve and brain tissue could also be regenerated by using METH1 or METH2 polynucleotides or polypeptides to proliferate and differentiate nerve cells. Diseases that could be treated using this method include central and peripheral nervous system diseases, neuropathies, or mechanical and traumatic disorders (e.g., spinal cord disorders, head trauma, cerebrovascular
25 disease, and stroke). Specifically, diseases associated with peripheral nerve injuries, peripheral neuropathy (e.g., resulting from chemotherapy or other medical therapies), localized neuropathies, and central nervous system diseases (e.g., Alzheimer's disease, Parkinson's disease, Huntington's disease, amyotrophic lateral sclerosis, and Shy-Drager syndrome), could all be treated using the METH1 or
30 METH2 polynucleotides or polypeptides.

Chemotaxis

METH1 or METH2 polynucleotides or polypeptides may have chemotaxis activity. A chemotactic molecule attracts or mobilizes cells (e.g., monocytes, fibroblasts, neutrophils, T-cells, mast cells, eosinophils, epithelial and/or endothelial cells) to a particular site in the body, such as inflammation, infection, or site of hyperproliferation. The mobilized cells can then fight off and/or heal the particular trauma or abnormality.

METH1 or METH2 polynucleotides or polypeptides may increase chemotactic activity of particular cells. These chemotactic molecules can then be used to treat inflammation, infection, hyperproliferative disorders, or any immune system disorder by increasing the number of cells targeted to a particular location in the body. For example, chemotactic molecules can be used to treat wounds and other trauma to tissues by attracting immune cells to the injured location. As a chemotactic molecule, METH1 or METH2 could also attract fibroblasts, which can be used to treat wounds.

It is also contemplated that METH1 or METH2 polynucleotides or polypeptides may inhibit chemotactic activity. These molecules could also be used to treat disorders. Thus, METH1 or METH2 polynucleotides or polypeptides could be used as an inhibitor of chemotaxis.

Binding Activity

METH1 or METH2 polypeptides may be used to screen for molecules that bind to METH1 or METH2 or for molecules to which METH1 or METH2 binds. The binding of METH1 or METH2 and the molecule may activate (agonist), increase, inhibit (antagonist), or decrease activity of the METH1 or METH2 or the molecule bound. Examples of such molecules include antibodies, oligonucleotides, proteins (e.g., receptors), or small molecules.

Preferably, the molecule is closely related to the natural ligand of METH1 or METH2, e.g., a fragment of the ligand, or a natural substrate, a ligand, a structural or functional mimetic. (See, Coligan *et al.*, *Current Protocols in*

Immunology 1(2):Chapter 5 (1991).) Similarly, the molecule can be closely related to the natural receptor to which METH1 or METH2 binds, or at least, a fragment of the receptor capable of being bound by METH1 or METH2 (e.g., active site). In either case, the molecule can be rationally designed using known techniques.

Preferably, the screening for these molecules involves producing appropriate cells which express METH1 or METH2, either as a secreted protein or on the cell membrane. Preferred cells include cells from mammals, yeast, *Drosophila*, or *E. coli*. Cells expressing METH1 or METH2 (or cell membrane containing the expressed polypeptide) are then preferably contacted with a test compound potentially containing the molecule to observe binding, stimulation, or inhibition of activity of either METH1 or METH2 or the molecule.

The assay may simply test binding of a candidate compound to METH1 or METH2, wherein binding is detected by a label, or in an assay involving competition with a labeled competitor. Further, the assay may test whether the candidate compound results in a signal generated by binding to METH1 or METH2.

Alternatively, the assay can be carried out using cell-free preparations, polypeptide/molecule affixed to a solid support, chemical libraries, or natural product mixtures. The assay may also simply comprise the steps of mixing a candidate compound with a solution containing METH1 or METH2, measuring METH1 or METH2/molecule activity or binding, and comparing the METH1 or METH2/molecule activity or binding to a standard.

Preferably, an ELISA assay can measure METH1 or METH2 level or activity in a sample (e.g., biological sample) using a monoclonal or polyclonal antibody. The antibody can measure METH1 or METH2 level or activity by either binding, directly or indirectly, to METH1 or METH2 or by competing with METH1 or METH2 for a substrate.

All of these above assays can be used as diagnostic or prognostic markers. The molecules discovered using these assays can be used to treat disease or to

bring about a particular result in a patient (e.g., blood vessel growth) by activating or inhibiting the METH1 or METH2 molecule. Moreover, the assays can discover agents which may inhibit or enhance the production of METH1 or METH2 from suitably manipulated cells or tissues.

5 Therefore, the invention includes a method of identifying compounds which bind to METH1 or METH2 comprising the steps of: (a) incubating a candidate binding compound with METH1 or METH2; and (b) determining if binding has occurred. Moreover, the invention includes a method of identifying agonists/antagonists comprising the steps of: (a) incubating a candidate
10 compound with METH1 or METH2, (b) assaying a biological activity, and (b) determining if a biological activity of METH1 or METH2 has been altered.

Other Activities

 METH1 or METH2 polypeptides or polynucleotides may also increase or decrease the differentiation or proliferation of embryonic stem cells, besides, as
15 discussed above, hematopoietic lineage.

 METH1 or METH2 polypeptides or polynucleotides may also be used to modulate mammalian characteristics, such as body height, weight, hair color, eye color, skin, percentage of adipose tissue, pigmentation, size, and shape (e.g., cosmetic surgery). Similarly, METH1 or METH2 polypeptides or polynucleotides
20 may be used to modulate mammalian metabolism affecting catabolism, anabolism, processing, utilization, and storage of energy.

 METH1 or METH2 polypeptides or polynucleotides may be used to change a mammal's mental state or physical state by influencing biorhythms, circadian rhythms, depression (including depressive disorders), tendency for
25 violence, tolerance for pain, reproductive capabilities (preferably by Activin or Inhibin-like activity), hormonal or endocrine levels, appetite, libido, memory, stress, or other cognitive qualities.

 METH1 or METH2 polypeptides or polynucleotides may also be used as a food additive or preservative, such as to increase or decrease storage

capabilities, fat content, lipid, protein, carbohydrate, vitamins, minerals, cofactors or other nutritional components.

Having generally described the invention, the same will be more readily understood by reference to the following examples, which are provided by way of illustration and are not intended as limiting.

Cancer Diagnosis and Prognosis

It is believed that certain tissues in mammals with cancer express significantly diminished levels of the METH1 or METH2 protein and mRNA encoding the METH1 or METH2 protein when compared to a corresponding "standard" mammal, i.e., a mammal of the same species not having the cancer. Further, it is believed that diminished levels of the METH1 or METH2 protein can be detected in certain body fluids (e.g., sera, plasma, urine, and spinal fluid) from mammals with cancer when compared to sera from mammals of the same species not having the cancer. Thus, the invention provides a diagnostic method useful during tumor diagnosis, which involves assaying the expression level of the gene encoding the METH1 protein in mammalian cells or body fluid and comparing the gene expression level with a standard METH1 gene expression level, whereby a decrease in the gene expression level under the standard is indicative of certain tumors. The invention also provides a diagnostic method useful during tumor diagnosis, which involves assaying the expression level of the gene encoding the METH2 protein in mammalian cells or body fluid and comparing the gene expression level with a standard METH2 gene expression level, whereby a decrease in the gene expression level under the standard is indicative of certain tumors.

Where a tumor diagnosis has already been made according to conventional methods, the present invention is useful as a prognostic indicator, whereby patients exhibiting diminished METH1 or METH2 gene expression will experience a worse clinical outcome relative to patients expressing the gene at a lower level.

By "assaying the expression level of the gene encoding the METH1 or METH2 protein" is intended qualitatively or quantitatively measuring or estimating the level of the METH1 or METH2 protein or the level of the mRNA encoding the METH1 or METH2 protein in a first biological sample either directly (e.g., by determining or estimating absolute protein level or mRNA level) or relatively (e.g., by comparing to the METH1 or METH2 protein level or mRNA level in a second biological sample).

Preferably, the METH1 or METH2 protein level or mRNA level in the first biological sample is measured or estimated and compared to a standard METH1 or METH2 protein level or mRNA level, the standard being taken from a second biological sample obtained from an individual not having the cancer. As will be appreciated in the art, once a standard METH1 or METH2 protein level or mRNA level is known, it can be used repeatedly as a standard for comparison.

By "biological sample" is intended any biological sample obtained from an individual, cell line, tissue culture, or other source which contains METH1 or METH2 protein or mRNA. Biological samples include mammalian body fluids (such as sera, plasma, urine, synovial fluid and spinal fluid) which contain secreted mature METH1 or METH2 protein, and adrenal, thyroid, stomach, brain, heart, placenta, lung, liver, muscle, kidney, pancreas, testis and ovarian tissue (for METH1); and prostate, small intestine, colon, brain and lung tissue (for METH2).

The present invention is useful for detecting cancer in mammals. In particular the invention is useful during diagnosis of the of following types of cancers in mammals: breast, ovarian, prostate, liver, lung, pancreatic, colon, and testicular. Preferred mammals include monkeys, apes, cats, dogs, cows, pigs, horses, rabbits and humans. Particularly preferred are humans.

Total cellular RNA can be isolated from a biological sample using the single-step guanidinium-thiocyanate-phenol-chloroform method described in Chomczynski and Sacchi, *Anal. Biochem.* 162:156-159 (1987). Levels of mRNA encoding the METH1 or METH2 protein are then assayed using any appropriate method. These include Northern blot analysis (Harada *et al.*, *Cell* 63:303-312

(1990)), S1 nuclease mapping (Fujita *et al.*, *Cell* 49:357- 367 (1987)), the polymerase chain reaction (PCR), reverse transcription in combination with the polymerase chain reaction (RT-PCR) (Makino *et al.*, *Technique* 2:295-301 (1990)), and reverse transcription in combination with the ligase chain reaction (RT-LCR).

Assaying METH1 or METH2 protein levels in a biological sample can occur using antibody-based techniques. For example, METH1 or METH2 protein expression in tissues can be studied with classical immunohistological methods (Jalkanen, M., *et al.*, *J. Cell. Biol.* 101:976-985 (1985); Jalkanen, M., *et al.*, *J. Cell. Biol.* 105:3087-3096 (1987)).

Other antibody-based methods useful for detecting METH1 or METH2 protein gene expression include immunoassays, such as the enzyme linked immunosorbent assay (ELISA) and the radioimmunoassay (RIA).

Suitable labels are known in the art and include enzyme labels, such as, glucose oxidase, and radioisotopes, such as iodine (^{125}I , ^{121}I), carbon (^{14}C), sulfur (^{35}S), tritium (^3H), indium (^{112}In), and technetium ($^{99\text{m}}\text{Tc}$), and fluorescent labels, such as fluorescein and rhodamine, and biotin.

Modes of administration

It is recognized that an increase in the vascular supply plays a central role in tumor progression and metastasis; therefore, inhibitors of angiogenesis can prove effective as adjuvant therapy for cancer patients. Some of the currently recognized angiogenic suppressors are poor candidates for systemic treatment due to severe collateral effect. The present inventors have found that METH1 and METH2 are potent inhibitors of angiogenesis both *in vitro* and *in vivo*. The advantage of METH1 and METH1 is that these inhibitors are normally associated with suppression of physiological angiogenesis; therefore, they offer lack of toxicity and endothelial specificity over other angiogenic inhibitors. Furthermore,

METH1 and METH2 present a restricted pattern of expression providing a possible advantage on organ specificity.

Accordingly, the polypeptides of the present invention may be employed to treat cancer. The METH1 and METH2 polypeptides of the present invention can also be used to treat individuals with other disorders that are related to angiogenesis, including abnormal wound healing, inflammation, rheumatoid arthritis, psoriasis, endometrial bleeding disorders, diabetic retinopathy, some forms of macula degeneration, hemangiomas, and arterial-venous malformations.

Thus, the invention provides a method of inhibiting angiogenesis in an individual comprising administering to such an individual a pharmaceutical composition comprising an effective amount of an isolated METH1 polypeptide of the invention, effective to increase the METH1 activity level in such an individual. The invention also provides a method of inhibiting angiogenesis in an individual comprising administering to such an individual a pharmaceutical composition comprising an effective amount of an isolated METH2 polypeptide of the invention, effective to increase the METH2 activity level in such an individual.

METH1 polypeptides which may be used to inhibit angiogenesis in this manner include: METH1 polypeptide encoded by the deposited cDNA including the leader; the mature METH1 polypeptide encoded by the deposited the cDNA minus the leader (i.e., the mature protein); a polypeptide comprising amino acids about 1 to about 950 in SEQ ID NO:2; a polypeptide comprising amino acids about 2 to about 950 in SEQ ID NO:2; a polypeptide comprising amino acids about 29 to about 950 in SEQ ID NO:2; a polypeptide comprising amino acids about 30 to about 950 in SEQ ID NO:2; a polypeptide comprising the metalloprotease domain of METH1, amino acids 235 to 459 in SEQ ID NO:2; a polypeptide comprising the disintegrin domain of METH1, amino acids 460 to 544 in SEQ ID NO:2; a polypeptide comprising the first TSP-like domain of METH1, amino acids 545 to 598 in SEQ ID NO:2; a polypeptide comprising the second TSP-like domain of METH1, amino acids 841 to 894 in SEQ ID NO:2; a

polypeptide comprising the third TSP-like domain of METH1, amino acids 895 to 934 in SEQ ID NO:2; a polypeptide comprising amino acids 536 to 613 in SEQ ID NO:2; and a polypeptide comprising amino acids 549 to 563 in SEQ ID NO:2.

METH2 polypeptides which may be used to inhibit angiogenesis in this manner include: the METH2 polypeptide encoded by the deposited cDNA including the leader; the mature METH2 polypeptide encoded by the deposited the cDNA minus the leader (i.e., the mature protein); a polypeptide comprising amino acids about 1 to about 890 in SEQ ID NO:4; a polypeptide comprising amino acids about 2 to about 890 in SEQ ID NO:4; a polypeptide comprising amino acids about 24 to about 890 in SEQ ID NO:4; a polypeptide comprising amino acids about 112 to about 890 in SEQ ID NO:4; a polypeptide comprising the metalloprotease domain of METH2, amino acids 214 to 439 in SEQ ID NO:4; a polypeptide comprising the disintegrin domain of METH2, amino acids 440 to 529 in SEQ ID NO:4; a polypeptide comprising the first TSP-like domain of METH2, amino acids 530 to 583 in SEQ ID NO:4; a polypeptide comprising the second TSP-like domain of METH2, amino acids 837 to 890 in SEQ ID NO:4; a polypeptide comprising amino acids 280 to 606 in SEQ ID NO:4; and a polypeptide comprising amino acids 529 to 548 in SEQ ID NO:4.

As a general proposition, the total pharmaceutically effective amount of METH1 or METH2 polypeptide administered parenterally per dose will be in the range of about 1 µg/kg/day to 10 mg/kg/day of patient body weight, although, as noted above, this will be subject to therapeutic discretion. More preferably, this dose is at least 0.01 mg/kg/day, and most preferably for humans between about 0.01 and 1 mg/kg/day for the polypeptide. If given continuously, the METH1 or METH2 polypeptide is typically administered at a dose rate of about 1 µg/kg/hour to about 50 µg/kg/hour, either by 1-4 injections per day or by continuous subcutaneous infusions, for example, using a mini-pump. An intravenous bag solution may also be employed.

Pharmaceutical compositions containing the METH1 or METH2 of the invention may be administered orally, rectally, parenterally, intracistemally,

intravaginally, intraperitoneally, topically (as by powders, ointments, drops or transdermal patch), buccally, or as an oral or nasal spray. By "pharmaceutically acceptable carrier" is meant a non-toxic solid, semisolid or liquid filler, diluent, encapsulating material or formulation auxiliary of any type. The term "parenteral" as used herein refers to modes of administration which include intravenous, intramuscular, intraperitoneal, intrasternal, subcutaneous and intraarticular injection and infusion.

Chromosome Assays

The nucleic acid molecules of the present invention are also valuable for chromosome identification. The sequence is specifically targeted to and can hybridize with a particular location on an individual human chromosome. The mapping of DNAs to chromosomes according to the present invention is an important first step in correlating those sequences with genes associated with disease.

In certain preferred embodiments in this regard, the cDNA herein disclosed is used to clone genomic DNA of a METH1 or METH2 protein gene. This can be accomplished using a variety of well known techniques and libraries, which generally are available commercially. The genomic DNA then is used for *in situ* chromosome mapping using well known techniques for this purpose.

In addition, in some cases, sequences can be mapped to chromosomes by preparing PCR primers (preferably 15-25 bp) from the cDNA. Computer analysis of the 3' untranslated region of the gene is used to rapidly select primers that do not span more than one exon in the genomic DNA, thus complicating the amplification process. These primers are then used for PCR screening of somatic cell hybrids containing individual human chromosomes.

Fluorescence *in situ* hybridization ("FISH") of a cDNA clone to a metaphase chromosomal spread can be used to provide a precise chromosomal location in one step. This technique can be used with probes from the cDNA as

short as 50 or 60 bp. For a review of this technique, see Verma *et al.*, *Human Chromosomes: A Manual Of Basic Techniques*, Pergamon Press, New York (1988).

5 Once a sequence has been mapped to a precise chromosomal location, the physical position of the sequence on the chromosome can be correlated with genetic map data. Such data are found, for example, in V. McKusick, *Mendelian Inheritance In Man*, available on-line through Johns Hopkins University, Welch Medical Library. The relationship between genes and diseases that have been mapped to the same chromosomal region are then identified through linkage analysis (coinheritance of physically adjacent genes).

10 Next, it is necessary to determine the differences in the cDNA or genomic sequence between affected and unaffected individuals. If a mutation is observed in some or all of the affected individuals but not in any normal individuals, then the mutation is likely to be the causative agent of the disease.

15 Having generally described the invention, the same will be more readily understood by reference to the following examples, which are provided by way of illustration and are not intended as limiting.

Examples

Example 1: Identification and cloning of METH1 and METH2

20 To search for novel genes with TSP-like domains, a large human cDNA database consisting of approximately 900,00 expressed sequence tags (ESTs) was screened for sequences homologous to the second type I repeat of TSP1. Several ESTs were predicted to encode proteins with TSP-like domains. Two cDNA clones originated from human heart and lung libraries were further sequenced and
25 chosen for functional analysis.

The amino-terminal end of METH1 was obtained using 5' rapid amplification of cDNA ends (RACE) PCR technique (Marathon cDNA amplification kit, Clontech) according to manufacturer instructions. The amino-terminal end of METH2 was obtained partially through 5'RACE PCR and later confirmed and completed by genomic screening. For the genomic screen, BAC clones (Genome Systems) were initially identified by PCR. Positive BAC clones containing 150-200bp of sequence were subsequently subcloned into pGEM vector as small fragments and sequenced.

Analysis and comparison of the deduced amino acid sequence with the GenBank, EMBL and SwissProt databases suggested that these genes belong to a new family of metalloproteases with homology to the reprolysin family in their NH₂-terminal end and with several TSP-like motifs in the COOH-terminal end. These cDNAs were named METH1 and METH2; ME, for metalloprotease and TH, for thrombospondin. The mouse homologue of METH1 was identified and named ADAMTS1 (Kuno, K., *et al.*, *J. Biol. Chem.* 272:556-562 (1997)). Direct comparison of the human and mouse sequences revealed a high level of conservation (83.4% amino acid identity). Thus far no homologues for METH2 have been identified.

Interestingly, a recently identified protein named pNPI (procollagen I N-proteinase; Colidge, A., *et al.*, *Proc. Natl. Acad. Sci. USA* 94:2374-2379 (1997)) showed a striking sequence and structural similarity to METH1 and METH2 (Figure 3). As the novel proteins described here, pNPI also contains metalloproteinase (reprolysin subfamily) and TSP domains at the carboxy-terminal end. Although the sequence for pNPI is of bovine origin, sequence alignment revealed identical structural features. The amino acid similarity between METH1 and METH2 is 51.7%, and between METH1 or METH2 and pNPI the homology is lesser 33.9% and 36.3%, respectively.

Sequence analysis showed that the ORF of METH1 and METH2 coded for proteins of 950 and 890 amino acids, respectively. In all three proteins, the NH₂ terminal end contains a putative signal peptide followed by another putative

-115-

transmembrane domain around amino acid 300, deduced from the hydrophilicity plots. It is not clear whether these proteins are bound to the membrane. However, given preliminary data, it is more likely that this second transmembrane domain will consist of a hydrophobic pocket and that METH1, METH2 and pNPI are in fact secreted proteins. The NH₂-terminal end past the signal peptide has homology to the superfamily of zinc metalloproteases and can be subdivided in a prodomain, a metalloprotease domain, and a cysteine-rich region.

The double underlined sequence in METH1 and METH2 in Figure 3 localized at the boundary between the prodomain and the metalloprotease domain, are potential cleavage sites for mammalian subtilisins, such as furins (Barr, 1991). Proteolytical processing occurs in SVMPs to yield soluble metalloproteases and disintegrins (Bjarnason, J.B. & Fox, J.W., *Methods Enzymol.* 248:345-368 (1995)) and has also been detected in some ADAMs (reviewed by Wolsberg, T.G. & White, J.M., *Developmental Biology* 180:389-401 (1996)). At this point, preliminary experiments suggest that proteolytical processing occurs, at least in METH1. Additionally, both METH1 and METH2 present a Zn²⁺-binding site (dotted line in Figure 3) that is presumed to be catalytically active due to the conservation of certain functionally important amino acids (Rawlings, N.D. & Barrett, A.J., *Methods Enzymol.* 248:183-228 (1995)) suggesting that these proteins may be active proteases. Following the metalloprotease domain, there is a cysteine-rich region which contains two putative disintegrin loops (Wolsberg, T.G. & White, J.M., *Developmental Biology* 180:389-401 (1996)) (marked by arrows in Figure 3). Disintegrin domains are found within the superfamily of metalloproteases in snake venom metalloproteases (SVMPs) and ADAMs (mammalian proteins containing a disintegrin and a metalloprotease domain) and have a possible function inhibiting binding of integrins to their ligands in SVMPs. Conversely, the ADAM-disintegrin-like domain, as part of membrane anchored proteins, may promote rather than disrupt, cell-cell interactions (Wolsberg, T.G. & White, J.M., *Developmental Biology* 180:389-401 (1996)). The TSP-like domains are located in the COOH-half of METH1 and METH2 proteins. METH1

contains two conserved TSP domains separated by a spacer region with unknown function, and a subdomain with less homology, and only 5 cysteines, following the second anti-angiogenic region. METH2 contains two TSP domains separated by the spacer region. The alignment of the TSP-like domains of METH1 and METH2 with those of TSP1 and TSP2 are shown in Figure 5. The homology varies between 19.2% to 52% amino acid similarity among all the TSP repeats. The cysteines, numbered 1 to 6, and the tryptophans, labeled by asterisks, are highly conserved.

Southern blot of human genomic DNA revealed the presence of METH1 and METH2 in the genome. METH1 and METH2 probes revealed bands of different size suggesting that they are transcribed from different genes.

The consensus sequence for the type I repeats includes 16 residues with 6 perfectly conserved cysteines. Typically it begins with the sequence motif WSXWS (SEQ ID NO:82) that has also been shown to bind to heparin (Guo, N., *et al.*, *J. Biol. Chem.* 267:19349-19355 (1992)). The affinity of this region to heparin has been proposed to the part of the anti-angiogenic activity of TSP-1 (Guo, N., *et al.*, *J. Peptide Res.* 49 (1997)). Among the five members of the TSP family of proteins, only TSP-1 and TSP-2 inhibit angiogenesis and contain the type I repeats (Tolsma, S.S., *et al.*, *J. Cell. Biol.* 122:497-511 (1993); Kyriakides, T.R., *et al.*, *J. Cell Biol.* 140:419-430 (1998)). The type I or properdin repeats were probably added to the precursor of TSP1 and 2 by exon shuffling between 500 and 900 years ago (Adams, J., *et al.*, *The Thrombospondin Gene Family*, 1 Ed. Molecular Biology Intelligence Unit (Springer, Ed.), R.G. Landes Company, Germany (1995)). It is likely that the acquisition of this domain provided the precursor of TSP1 and TSP2 with functions, such as regulation of new vessel formation. More recently, BAI-1 (brain angiogenic inhibitor-1), a protein isolated from a brain library for its ability to be regulated by p53, has also been shown to contain the type I repeat of TSP-1 and to provide anti-angiogenic potential to this molecule (Nishimori, H., *et al.*, *Oncogene* 15:2145-2150 (1997)). Nevertheless, it appears that additional sequences or context are also important, since other

proteins containing the type I repeats appear not to have clear or more established anti-angiogenic properties such as: properdin, F-spondin, and other members of the complement family.

Because of the presence of TSP-repeats in METH1 and METH2, along with their anti-angiogenic properties, these proteins were originally considered members of the TSP superfamily. Nevertheless, they have no additional homology to other TSPs, and in fact, the similarity to TSP1 and TSP2 is restricted to the type I repeats. Furthermore, the proteins also have strong sequence and structural homology to members of the ADAM family. These features led Kuno and colleagues to name ADAMTS to the mouse homolog of METH1 (Kuno, K., *et al.*, *J. Biol. Chem.* 272:556-562 (1997)). The recent identification of pNPI and its striking sequence homology to the proteins here described, prompt all these three proteins to be grouped in a subfamily named metallospondins. At this point, it is not clear whether pNIP has anti-angiogenic properties or whether METH1 and/or METH2 participate in the cleavage of the amino terminal pro-peptide of $\alpha 1(I)$ procollagen.

Example 2: Northern and Southern blot analysis

Total RNA was purified from cells by guanidinium-isothiocyanate extraction, as previously described (Chomczynski, P. & Sacchi, N., *Anal. Biochem.* 162:156-159 (1987)) Poly(A)+RNA was extracted using a Boehringer Mannheim (BMB, Indianapolis, IN) kit according to the manufacturer conditions. Other poly(A)+RNA blots were purchased from Clontech (Palo Alto, CA). Pre-hybridization was performed in a solution containing: 50% formamide, 6X SSPE, 1X Denhardt's solution, 0.1% SDS and 100 μ g/ml of heat denatured salmon sperm DNA for 12-18h at 42°C. Hybridization with labeled cDNA probes proceeded in the same solution at 42°C for 12-18h. TSP1 and METH1 probes corresponded to the entire human cDNAs. METH2 probe corresponded to a *KpnI-EcoRI* fragment from the human cDNA. A 1.3Kb *PstI* fragment of the glyceraldehyde-3-

phosphate-dehydrogenase (GPDH) was used to normalize for loading and transfer efficiency. Membranes were exposed to Kodak Biomax MS film (Kodak, New Haven, CT).

For Southern blots, human genomic DNA, purchased from Promega (Madison, WI), was heated at 65°C for 10 min and digested with *EcoRI* and *PstI* overnight at 37°C. 5µg of digested DNA was separated in a 1% agarose gel, transferred to a nytran membrane and cross-linked by ultraviolet light. cDNA probes, as well as, prehybridization and hybridization conditions were identical to those described for Northern blots. Blots were washed with high stringency (0.2X SSC, 0.2% SDS at 50°C).

The expression pattern of METH1 and METH2 was examined in both adult and embryonic tissues. Northern blot analysis was performed under high-stringency conditions with blots that included poly(A)+RNA from human tissues. METH1 and METH2 transcripts revealed a single band of 4.6 and 3.7Kb, respectively. Abundant METH1 mRNA expression was observed in adrenal, heart, placenta, followed by skeletal muscle, thyroid and stomach. From the embryonic tissues analyzed, kidney showed the highest expression of METH1 mRNA. Nevertheless, weaker expression of METH1 mRNA was seen in all tissues analyzed. Distribution of METH2 mRNA was more restricted and weaker than that of METH1. The highest expression was seen in lung, both embryonic and adult. Interestingly, METH1 and METH2 expression do not appear to overlap. In combination, the structural similarities and their pattern of expression suggest functional redundancy yet different transcriptional regulation. The expression levels of TSP1 transcripts in the same blots were also analyzed, for purpose of comparison. TSP1 mRNA highest expression was seen in the adult placenta and in all embryonic tissues analyzed. In contrast to METH1 and METH2 we observed constant levels of TSP1 transcript in all the other tissues examined.

The cell type distribution was also studied by Northern blot analysis of poly(A)+RNA. METH1 mRNA was detectable, at low levels, in dermal

fibroblasts, vascular smooth muscle, endometrial stromal cells, and in two cancer cell lines, HeLa and G631, an adenocarcinoma and a melanoma, respectively. METH2 mRNA was detected only on SW480, a colon carcinoma cell line, but no expression was seen in any other of the cell lines or primary strains analyzed.

5 The possibility that groups of angiogenic and anti-angiogenic factors regulate vascular network formation in specific organs has been a frequently discussed hypothesis likely to be true, yet unproven. The expression patterns of METH1 and METH2, which are clearly distinct and almost non-overlapping, were puzzling, at least with concern to overall levels. TSP1 and TSP2 also share
10 identical structure, high level of amino acid similarity, yet their pattern of expression differs significantly (Iruela-Arispe, M.L., *Dev. Dyn.* 197:40-56 (1993)). The differences are likely based on dissimilar cis-acting elements in their promoters and different regulatory mechanisms, as previously suggested. Although the promoters for METH1 and 2 have not been characterized, it is likely
15 that they provide unique features for the regulation of each gene. Nevertheless, the possibility that one motif, the anti-angiogenic / type I repeat, with demonstrated anti-angiogenic properties is present in several proteins with different tissue specificities is appealing. Alternatively, the small differences in sequence between closely related members of the same family could possess
20 significance that goes beyond functional redundancy. In the case of TSP1 and TSP2, aside from the striking structural similarities and perhaps having functionally common anti-angiogenic properties, TSP1 and TSP2 also appear to display functions of their own and not likely shared by their similar relative. This became evident with the outcome of the two knock-outs for these genes. TSP1
25 null animals exhibited primarily lung disorders (Lawler, J., *et al.*, *J. Clin. Invest.* 101:982-992 (1998)) and secondarily vascular abnormalities, but only under specific pathological settings or on a restricted set of organs. In contrast TSP2 knock-out mice exhibited unpredicted collagen assembly anomalies, with carry-on consequences to the skin, tendons, and bone (Kyriakides, T.R., *et al.*, *J. Cell Biol.*
30 140:419-430 (1998)). In addition, these animals also appear to have overall

increase in capillary density in the dermis. It is not understood how the resemblance between the newly described members of the metallospondin family translate functionally. Clearly, pNIP has been shown to display active proteolytic activity by cleaving the N-terminus of type I procollagen (Colidge, A., *et al.*, *Proc. Natl. Acad. Sci. USA* 94:2374-2379 (1997)).

5 A second region of functional interest corresponds to the disintegrin domain. This domain has been more fully characterized in related members of the snake venom metalloproteases that have been shown to bind to α IIb β 3 and inhibit platelet interaction blocking coagulation (Pfaff, M., *et al.*, *Cell Adhes Commun.* 2:491-501 (1994); Usami, Y., *et al.*, *Biochem. Biophys. Res. Commun.* 201:331-10 339 (1994)). The disintegrin motif consists of a thirteen to fifteen domain which frequently contain an RGD or a negatively charged residue at the position of the aspartic acid. The RGD, or equivalent, binds to integrins and serve as antagonist or signaling ligands (Wolsberg, T.G. & White, J.M., *Developmental Biology* 15 180:389-401 (1996)). METH2, but not METH1, has an RGD sequence located amino-terminal to the disintegrin domain. In addition, both molecules present relatively high, but not perfect, degree of conservation of cysteines within the disintegrin motif. This appears to display an important role in the tertiary structure of this region and its ability to interact with integrins. In addition, some 20 of these domains have been shown to act as functional adhesion molecules, particularly those with transmembrane regions (Wolsberg, T.G. & White, J.M., *Developmental Biology* 180:389-401 (1996)). It is unlikely that this will be the case for METH1 and METH2, since both these proteins appear to be secreted.

Example 3: Expression and purification of recombinant proteins

25 Recombinant constructs for expression of truncated fusion proteins were as follows: (1) pRSET-METH1-Type I: METH1 nt 1605-1839 (from the start codon) was amplified by polymerase chain reaction using the following primers: 5'-GCA TTT TGG ATC CGC CTT TTC ATG-3' (SEQ ID NO:78) and 5'-GTT

GTG TGC TGC AGA TTG TTC C-3' (SEQ ID NO:79). The amplified fragment was then subcloned into the *Bam*HI and *Pst*I sites of the pRSET vector; (2) pGEX-METH1-TSP was generated by ligating the *Bam*HI-*Eco*RI fragment from the pRSET-METH1-TSP into the *Sma*I site of the pGEX-5X vector (Pharmacia Biotech Inc., Piscataway, NJ) by blunt-end ligation; (3) pGEX-1.0-METH2: the fragment nt 838-1818 of METH2 cDNA (from the start codon) was ligated into *Bam*HI-*Eco*RI sites of pGEM-2TK. The METH2 fragment was amplified by PCR using the following primers: 5'-GAAAAATGGGGATCCGAGGTG-3' (SEQ ID NO:80) and 5'-GCAGGAGAATTCCGTCCATG-3' (SEQ ID NO:81) to generate *Bam*HI and *Eco*RI restriction sites; (4) pGEX-METH2-TSP: a 0.5Kb *Xma*I-*Eco*RI fragment isolated from pGEX-1.0-METH2 was subcloned into the *Xma*I and *Eco*RI sites of pGEX-2TK vector. All constructs were sequenced to verify sequence fidelity and correct open reading frame.

The recombinant proteins were named 6H-METH1, the recombinant protein expressed with the plasmid pRSET-METH1-TSP, GST-METH1, the protein expressed with the plasmid pGEX-METH1-TSP and GST-METH2, the protein expressed with the plasmid pGEX-METH2-TSP.

Expression plasmids were transformed into BL21:DE3 *E. coli* strain (Stratagene Cloning Systems, La Jolla, CA) and fusion proteins were induced following manufacturer recommendations. Briefly, induced bacteria pellets were resuspended in PBS and sonicated on ice for 1 min. The suspension was, subsequently, incubated at RT for 20min in the presence of 1% triton X-100 and centrifuged at 4°C. Histidine tagged fusion proteins were then purified on Ni-NTA beads (Qiagen, Chatsworth, CA) by incubating 20ml of supernatant with 1ml of beads (50% slurry) for 2h at 4°C. The suspension was transferred into a column and washed with 10 columns volume of PBS containing 10mM imidazole, followed by 50mM imidazole and finally 100mM imidazole. The protein was eluted with 500mM imidazole in PBS. Fractions containing the recombinant protein were dialyzed against phenol-red free DMEM. Samples were centrifuged for 30min at 4°C, part of the protein was not soluble and was lost during

centrifugation. The supernatant was stored at -70°C and used for proliferation, cornea pocket and chorioallantoic membrane (CAM) assays.

For purification of GST-fusion proteins, the extract was cleared by centrifugation and applied to a GST-affinity column (Pharmacia). The column
5 was washed with PBS-1% triton X-100 in the presence of 0.1mM reduced glutathione and, subsequently, with the same buffer in the presence of 0.5mM reduced glutathione. Fusion proteins were eluted with 10mM reduced glutathione in 50mM Tris-HCl, pH 7.5. Fractions containing the protein were dialyzed against DMEM, stored at -70°C and used for proliferation, cornea pocket and
10 chorioallantoic membrane (CAM) assays.

Integrity and purity of recombinant proteins was analyzed in 12.5% or 15% acrylamide gels stained with Coomassie blue.

A recombinant GST fusion protein containing the first two type I repeats of TSP was also dialyzed against DMEM before used in functional assays. Intact
15 TSP1 was purified from platelets as previously described (Roberts, D.D., *et al.*, *J. Tissue Cult. Methods* 16:217-222 (1994)).

To test the hypothesis that METH1 and METH2 TSP domains could function as regulators of angiogenesis recombinant fusion proteins were generated in bacteria. The constructs included the first TSP domain of METH1 or METH2.
20 This domain is the most conserved, 52% amino acid similarity with the second type I repeat of TSP1, (this domain contains a putative binding site for CD36). All recombinant proteins were isolated under native conditions to preserve their secondary structure as much as possible. 6H-METH1 and GST-METH1 contained the first TSP-like domain of METH1 fused to a histidine tag or a GST,
25 respectively. METH1 recombinant protein was made with two different tags because of purification and structural advantages. The differences in size are due to the size of the tag, 6KDa the histidine and 27KDa the GST. GST-METH2 contained the first TSP domain of METH2 also fused to a GST. A fragment corresponding to the last two type I repeats of TSP1, also fused to a GST, and

intact TSP1 purified from platelets were used as positive controls. In addition, GST alone was included in all experiments as negative control.

Example 4: TSP domains in METH1 and METH2 disrupt angiogenesis in vivo

Cornea pocket assay

5 Swiss Webster females and males, were purchased from Charles River (Boston, MA) and used between 8-10 weeks-old for implantation of the pellets. Cornea pockets were performed as described by Kenyon and colleagues (Kenyon, B.M., *et al.*, *Invest. Ophthalmol. Vis. Sci.* 37:1625-1632 (1996)) with few modifications. Briefly, a solution of 10 μ g of recombinant bFGF plus 5 mg of
10 sucralfate were mixed with 10 μ l of Hydron (200mg/ml in ethanol; New Brunswick, NJ) and the recombinant protein of interest (2 μ g). The suspension was then smeared onto a sterile nylon mesh square (pore size 500 μ m; Tetko Inc., Briarcliff Manor, NY) and allowed to dry for 30min. The fibers of the mesh were pulled to produce pellets of 500 μ m³ that were stored at -20°C. Uniformly sized
15 pellets were selected under a microscope and used for the assays.

Mice were anesthetized with Avertin. An incision was made in the cornea using a Nikon SMZ-U dissecting microscope with the aid of a surgical blade. A single pellet was implanted into the pocket. Five days after pellet implantation, corneal angiogenesis was evaluated and photographed.

20 CAM assay

Chorioallantoic membrane assays were performed on Leghorn chicken embryos (SPAFAS, MA) at 12-14 days of embryonic development. Matrigel (750 μ g/ml), VEGF (250ng/mesh) and the protein or peptide to be tested were mixed, placed onto nylon meshes (pore size 250 μ m; Tetko Inc.) and incubated
25 sequentially at 37°C for 30min and at 4°C for 2h to induce polymerization. A positive (matrigel and VEGF) and a negative (VEGF alone) control were also prepared for each CAM. Polymerized meshes were placed onto the third outer

region of the CAM and incubated for 24h. To visualize vessels, 400µl of fluorescein isothiocyanate dextran (10mg/ml, SIGMA) was injected in the chick blood stream. After 5-10min incubation, the chick was topically fixed with 3.7% formaldehyde for 5min. The meshes were then dissected and mounted onto slides. Fluorescence intensity was analyzed with a computer-assisted image program (NIH Image 1.59).

Peptides used on these assays were synthesized by Chiron (Raleigh, NC). Sequence corresponded to amino acids: P-TSP1, 430-447; P-METH1, 549-563; P-METH2, 529-548.

The evaluation of angiogenic or anti-angiogenic responses relies heavily on the sensitivity and specificity of the assays used to assess the response. To evaluate the anti-angiogenic activity of these fragments *in vivo*, two popular and well-accepted angiogenesis assays were used: the corneal pocket and the chorioallantoic membrane. The visibility, accessibility, and avascularity of the cornea are highly advantageous and facilitate the visualization of the neovascular response and the topical application of the test substances. A known amount of angiogenesis factor(s) is implanted, as a pellet, in a pocket made in the cornea eye. To test an angiogenesis inhibitor, the molecule is implanted with the stimulator in the same pellet, and the response is compared to the stimulator alone.

In these experiments, bFGF was used as the vascularization stimulator. Pellets containing the recombinant protein were implanted in mouse corneas and their ability to inhibit the bFGF-induced angiogenic response was compared to that of controls. When a bFGF pellet containing GST was implanted new capillary vessels grew from the cornea limbus, across the cornea and into the pellet within 5 days. In contrast, addition of GST-METH1 or GST-METH2 to the bFGF pellets completely abolished blood vessel growth. Table 4 contains a summary of the results obtained from 41 assays performed. Intact TSP1 purified from platelets and GST-TSP1 were used as positive controls. All assays were performed at identical concentrations, suggesting that METH1 and METH2 have similar potency to that of TSP1 in the inhibition of angiogenesis. In addition, when half

of the standard concentration was used, a weak, however noticeable response was seen, indicating a dose-dependent effect.

Table 4.
Activity of METH1 and METH2 recombinant proteins in the corneal pocket assay

bFGF Pellets	Vascularized corneas/Total corneas
Vehicle	5/5
TSP1	0/5
GST	11/11
GST-TSP1-TI	1/4
GST-METH1-TSP	0/8
GST-METH2-TSP	0/8

In the CAM assay, the angiogenic response is analyzed by measuring the number of vessels that grow within a matrix polymer containing the angiogenic growth factor. To determine whether recombinant METH1 and METH2 proteins inhibited neovascularization in the CAM assay induced by VEGF, a matrigel polymer containing VEGF and the recombinant protein were implanted in the CAM. Quantitative analysis of the experiments, which included three different polymers per treatment are shown in Figure 6A. Matrigels polymers containing VEGF plus 5 μ g of GST-METH1 or GST-METH2 caused greater than 80% inhibition in blood vessel growth. A similar potency was found using the GST recombinant protein derived from the type I repeats of TSP1. Furthermore, the anti-angiogenic effect of the TSP domains in METH1 and METH2 was dose-dependent with a complete inhibition of blood vessel growth when 15 μ g/ml of protein was used (Figure 6C and D). GST alone, at identical concentrations, had no significant effect on VEGF-stimulated angiogenesis.

Synthetic peptides from the second or the third type I repeats of human TSP1 can mimic that anti-angiogenic effects of the intact TSP1 (Tolsma, S.S., *et al.*, *J. Cell. Biol.* 122:497-511 (1993)). In fact, a 19-residue polypeptide was shown to be sufficient to block *in vivo* neovascularization in the rat cornea and to inhibit the bFGF-induced migration of cultured endothelial cells (Vogel, T., *et al.*, *J. Cell. Biochem.* 53:74-84 (1993); Tolsma, S.S., *et al.*, *J. Cell. Biol.* 122:497-511 (1993)). To test whether the same was true for the METH1 and METH2 TSP domains, peptides derived from the same region were synthesized and their anti-angiogenic activity was evaluated in the CAM assay. The results are shown in Figure 6B. Peptides derived from both the TSP domain of METH1 and METH2 blocked VEGF-induced angiogenesis similarly to that of TSP1. In contrast, scramble peptides had no significant effects.

Example 5: Proliferation assays

Human dermal endothelial cells (HDEC) were isolated and grown on Vitrogen™ coated petri-dishes in EBM (Clonetics, San Diego, CA) supplemented with 15% fetal calf serum, 25µg/ml cAMP, and 1µg/ml of hydrocortisone-21-acetate and were used from passages 3 to 6. Cells were made quiescent by incubation of confluent monolayers with phenol red-free EBM containing 0.2% BSA for 48h. Human dermal fibroblasts were isolated from neonatal foreskin and by enzymatic dissociation. Both fibroblasts and smooth muscle cells were maintained in DMEM supplemented with 10% fetal calf serum. Human mammary epithelial cells (HMEC) were purchased from Clonetics and maintained in the recommended media (mammary epithelial growth media, MEGM).

Quiescent human dermal endothelial cells, between passage 3 and 6, were plated on Vitrogen™ coated 24-well plates in EBM supplemented with 0.2% BSA, 0.1% fetal calf serum and 1 ng/ml of bFGF in the presence or absence of the recombinant protein and incubated at 5% CO₂ at 37°C for 48h. For vascular smooth muscle (VSM) and fibroblast proliferation assays, cells were incubated

under the same conditions but using DMEM instead of EBM. Human mammary epithelial cells were incubated on their growth media. A pulse of [³H]-Thymidine (1μCi/μl) was added during the last 4h prior harvesting. Cells were washed and fixed in 10% TCA. Incorporation of [³H]-thymidine was determined by scintillation counting, as previously described (Iruela-Arispe, M.L. & Sage, E.H., *J. Cell. Biochem.* 52:414 (1993)).

Statistical analysis were done using In-Stat software (Graph Pad Software) for Macintosh. Assuming normal distributions, data were analyzed by one-way ANOVA, followed by either T-test Dunnett test for comparisons between groups, or student-Newman-Kleus test for multiple comparisons between groups.

To gain insight into the mechanism by which METH1 and METH2 inhibit neovascularization, the direct effect of the purified recombinant fusion proteins on endothelial cell proliferation was tested. Serum-starved endothelial cells were plated into growth medium containing bFGF and FCS. Recombinant proteins (3μg/ml) were added at the same time of plating. 40% (GST-METH1), 45% (6H-GST) or 36% (GST-METH2) inhibition was observed, in contrast to a non-significant effect when GST alone was added. The recombinant protein from the type I repeats of TSP1 had similar inhibitory effects. (Figure 7A). Furthermore, suppression of proliferation mediated by METH1 or METH2 were dose-dependent, as shown in Figure 7E. The inhibition was observed as early as one day after treatment and the inhibitory effect was not toxic and reversible since the removal of the recombinant protein and subsequent addition of growth factor alone led to the resumption of endothelial cell proliferation.

The cell specificity of the anti-proliferative effects for METH1 and METH2 on the endothelium was evaluated by additional proliferation assays on a variety of non-endothelial cells. No significant inhibition of proliferation was seen on fibroblasts or smooth muscle cell cultures. In contrast, a non significant, but reproducible stimulation of proliferation for these two cell types could be observed. This result rules out the presence of any potential nonspecific inhibitor of cell growth in the recombinant protein preparations. On mammary epithelial

cell, however, METH1 and METH2 inhibited cell proliferation to the same degree as to endothelial cells. Interestingly, TSP1 also suppresses mammary epithelial cell proliferation both *in vitro* and in a transgenic model.

The possibility that METH1 and METH2 might act as disintegrins is consistent with their anti-angiogenic properties. Clearly blockade of $\alpha v\beta 3$ and $\beta 1$ integrins with antibodies has been shown to inhibit neovascularization both during development and in tumors (Brooks, P.C., *et al.*, *Cell* 85:683-693 (1996); Brooks, P.C., *et al.*, *Cell* 92:391-400 (1998); Senger, D.R., *et al.*, *Proc. Natl. Acad. Sci. USA* 94:13612-13617 (1997)). Integrins are essential for the mediation of both proliferative and migratory signals (Schwartz, M.A. & Ingber, D.E., *Mol. Biol. Cell* 5:389-393 (1994)), therefore interference with those signals can be highly deleterious to the angiogenic process. The angiogenic functional assays were performed with recombinant protein containing only the type I repeats in METH1 and METH2.

The mechanism of action of METH1 and METH2 with regards to their angio-inhibitory activity is not known. To date we have evidence that these proteins are secreted and bind to endothelial cells. Further investigations are guided towards the identification of receptors and signal transduction mechanisms. A likely hypothesis resulting from the lessons learned from TSP1 is that both METH1 and METH2 bind to CD36. Recently, this scavenger receptor has been implicated in the mediation of signals by which TSP-1 exert its anti-angiogenic effects (Dawson, D.W., *et al.*, *J. Cell. Biol.* 138:707-717 (1997)). Both the CSVTCG (SEQ ID NO:83) (Asch, A.S., *et al.*, *Nature* 262:1436-1439 (1993); Catimel, B., *et al.*, *Biochem. J.* 284:231-236 (1992)) and the GCQXR (SEQ ID NO:84) sequences have been proposed as primary binding motifs to CD36 (Dawson, D.W., *et al.*, *J. Cell. Biol.* 138:707-717 (1997)). METH1 and METH2 have almost entire conservation in both these regions. A complementary and also likely occurrence is binding of METH1 and METH2 to bFGF. Binding to heparin and bFGF has been proposed as part of the anti-angiogenic activity of TSP1 (Guo, N., *et al.*, *J. Peptide Res.* 49 (1997)). This property appears to be mediated

through the WSXWS (SEQ ID NO:82) motif, also conserved in METH1 and METH2. Future efforts will focus on the signals implicated in the anti-angiogenic properties mediated by these novel proteins and on their potential as proteases of the extracellular milieu.

5 ***Example 6: Isolation of the METH1 or METH2 cDNA Clone From the Deposited Sample***

Two approaches can be used to isolate METH1 or METH2 from the deposited sample. First, the deposited clone is transformed into a suitable host (such as XL-1 Blue (Stratagene)) using techniques known to those of skill in the art, such as those provided by the vector supplier or in related publications or patents. The transformants are plated on 1.5% agar plates (containing the appropriate selection agent, e.g., ampicillin) to a density of about 150 transformants (colonies) per plate. A single colony is then used to generate DNA using nucleic acid isolation techniques well known to those skilled in the art. (e.g.,
10 Sambrook et al., Molecular Cloning: A Laboratory Manual, 2nd Edit., (1989), Cold Spring Harbor Laboratory Press.)
15

Alternatively, two primers of 17-20 nucleotides derived from both ends of the SEQ ID NO:1 or SEQ ID NO:3 (i.e., within the region of SEQ ID NO:1 or SEQ ID NO:3 bounded by the 5' NT and the 3' NT of the clone) are synthesized and used to amplify the METH1 or METH2 cDNA using the deposited cDNA plasmids as templates. The polymerase chain reaction is carried out under routine conditions, for instance, in 25 µl of reaction mixture with 0.5 µg of the above cDNA template. A convenient reaction mixture is 1.5-5 mM MgCl₂, 0.01% (w/v) gelatin, 20 uM each of dATP, dCTP, dGTP, dTTP, 25 pmol of each primer and
20 0.25 Unit of Taq polymerase. Thirty five cycles of PCR (denaturation at 94 degree C for 1 min; annealing at 55 degree C for 1 min; elongation at 72 degree C for 1 min) are performed with a Perkin-Elmer Cetus automated thermal cycler.
25 The amplified product is analyzed by agarose gel electrophoresis and the DNA band with expected molecular weight is excised and purified. The PCR product

is verified to be the selected sequence by subcloning and sequencing the DNA product.

Several methods are available for the identification of the 5' or 3' non-coding portions of the METH1 or METH2 gene which may not be present in the deposited clones. These methods include but are not limited to, filter probing, clone enrichment using specific probes, and protocols similar or identical to 5' and 3' "RACE" protocols which are well known in the art. For instance, a method similar to 5' RACE is available for generating the missing 5' end of a desired full-length transcript. (Fromont-Racine *et al.*, *Nucleic Acids Res.* 21(7):1683-1684 (1993).)

Briefly, a specific RNA oligonucleotide is ligated to the 5' ends of a population of RNA presumably containing full-length gene RNA transcripts. A primer set containing a primer specific to the ligated RNA oligonucleotide and a primer specific to a known sequence of the METH1 or METH2 gene of interest is used to PCR amplify the 5' portion of the METH1 or METH2 full-length gene. This amplified product may then be sequenced and used to generate the full length gene.

This above method starts with total RNA isolated from the desired source, although poly-A⁺ RNA can be used. The RNA preparation can then be treated with phosphatase if necessary to eliminate 5' phosphate groups on degraded or damaged RNA which may interfere with the later RNA ligase step. The phosphatase should then be inactivated and the RNA treated with tobacco acid pyrophosphatase in order to remove the cap structure present at the 5' ends of messenger RNAs. This reaction leaves a 5' phosphate group at the 5' end of the cap cleaved RNA which can then be ligated to an RNA oligonucleotide using T4 RNA ligase.

This modified RNA preparation is used as a template for first strand cDNA synthesis using a gene specific oligonucleotide. The first strand synthesis reaction is used as a template for PCR amplification of the desired 5' end using a primer specific to the ligated RNA oligonucleotide and a primer specific to the known

sequence of the gene of interest. The resultant product is then sequenced and analyzed to confirm that the 5' end sequence belongs to the METH1 or METH2 gene.

Example 7: Bacterial Expression of METH1 or METH2

5 A METH1 or METH2 polynucleotide encoding a METH1 or METH2 polypeptide invention is amplified using PCR oligonucleotide primers corresponding to the 5' and 3' ends of the DNA sequence, as outlined in Example 5, to synthesize insertion fragments. The primers used to amplify the cDNA insert should preferably contain restriction sites, such as BamHI and XbaI, at the 5' end
10 of the primers in order to clone the amplified product into the expression vector. For example, BamHI and XbaI correspond to the restriction enzyme sites on the bacterial expression vector pQE-9. (Qiagen, Inc., Chatsworth, CA). This plasmid vector encodes antibiotic resistance (Amp^r), a bacterial origin of replication (ori), an IPTG-regulatable promoter/operator (P/O), a ribosome binding site (RBS), a
15 6-histidine tag (6-His), and restriction enzyme cloning sites. The pQE-9 vector is digested with BamHI and XbaI and the amplified fragment is ligated into the pQE-9 vector maintaining the reading frame initiated at the bacterial RBS. The ligation mixture is then used to transform the E. coli strain M15/rep4 (Qiagen, Inc.) which contains multiple copies of the plasmid pREP4, which expresses the
20 lacI repressor and also confers kanamycin resistance (Kan^r). Transformants are identified by their ability to grow on LB plates and ampicillin/kanamycin resistant colonies are selected. Plasmid DNA is isolated and confirmed by restriction analysis.

25 Clones containing the desired constructs are grown overnight (O/N) in liquid culture in LB media supplemented with both Amp (100 ug/ml) and Kan (25 ug/ml). The O/N culture is used to inoculate a large culture at a ratio of 1:100 to 1:250. The cells are grown to an optical density 600 (O.D.⁶⁰⁰) of between 0.4 and 0.6. IPTG (Isopropyl-B-D-thiogalacto pyranoside) is then added to a final

concentration of 1 mM. IPTG induces by inactivating the lacI repressor, clearing the P/O leading to increased gene expression.

Cells are grown for an extra 3 to 4 hours. Cells are then harvested by centrifugation (20 mins at 6000Xg). The cell pellet is solubilized in the chaotropic agent 6 Molar Guanidine HCl by stirring for 3-4 hours at 4 degree C. The cell debris is removed by centrifugation, and the supernatant containing the polypeptide is loaded onto a nickel-nitrilo-tri-acetic acid ("Ni-NTA") affinity resin column (available from QIAGEN, Inc., *supra*). Proteins with a 6 x His tag bind to the Ni-NTA resin with high affinity and can be purified in a simple one-step procedure (for details see: The QIAexpressionist (1995) QIAGEN, Inc., *supra*).

Briefly, the supernatant is loaded onto the column in 6 M guanidine-HCl, pH 8, the column is first washed with 10 volumes of 6 M guanidine-HCl, pH 8, then washed with 10 volumes of 6 M guanidine-HCl pH 6, and finally the polypeptide is eluted with 6 M guanidine-HCl, pH 5.

The purified METH1 or METH2 protein is then renatured by dialyzing it against phosphate-buffered saline (PBS) or 50 mM Na-acetate, pH 6 buffer plus 200 mM NaCl. Alternatively, the METH1 or METH2 protein can be successfully refolded while immobilized on the Ni-NTA column. The recommended conditions are as follows: renature using a linear 6M-1M urea gradient in 500 mM NaCl, 20% glycerol, 20 mM Tris/HCl pH 7.4, containing protease inhibitors. The renaturation should be performed over a period of 1.5 hours or more. After renaturation the proteins are eluted by the addition of 250 mM imidazole. Imidazole is removed by a final dialyzing step against PBS or 50 mM sodium acetate pH 6 buffer plus 200 mM NaCl. The purified METH1 or METH2 protein is stored at 4°C or frozen at -80°C.

In addition to the above expression vector, the present invention further includes an expression vector comprising phage operator and promoter elements operatively linked to a METH1 or METH2 polynucleotide, called pHE4a. (ATCC Accession Number 209645, deposited February 25, 1998.) This vector contains:

- 1) a neomycinphosphotransferase gene as a selection marker, 2) an *E. coli* origin

of replication, 3) a T5 phage promoter sequence, 4) two lac operator sequences, 5) a Shine-Delgarno sequence, and 6) the lactose operon repressor gene (*lacIq*). The origin of replication (*oriC*) is derived from pUC19 (LTI, Gaithersburg, MD). The promoter sequence and operator sequences are made synthetically.

5 DNA can be inserted into the pHEa by restricting the vector with *NdeI* and *XbaI*, *BamHI*, *XhoI*, or *Asp718*, running the restricted product on a gel, and isolating the larger fragment (the stuffer fragment should be about 310 base pairs). The DNA insert is generated according to the PCR protocol described in Example 5, using PCR primers having restriction sites for *NdeI* (5' primer) and *XbaI*,
10 *BamHI*, *XhoI*, or *Asp718* (3' primer). The PCR insert is gel purified and restricted with compatible enzymes. The insert and vector are ligated according to standard protocols.

The engineered vector could easily be substituted in the above protocol to express protein in a bacterial system.

15 ***Example 8: Purification of METH1 or METH2 Polypeptide from an Inclusion Body***

The following alternative method can be used to purify METH1 or METH2 polypeptide expressed in *E. coli* when it is present in the form of inclusion bodies. Unless otherwise specified, all of the following steps are conducted at
20 4-10°C.

Upon completion of the production phase of the *E. coli* fermentation, the cell culture is cooled to 4-10 degree C and the cells harvested by continuous centrifugation at 15,000 rpm (Heraeus Sepatech). On the basis of the expected yield of protein per unit weight of cell paste and the amount of purified protein
25 required, an appropriate amount of cell paste, by weight, is suspended in a buffer solution containing 100 mM Tris, 50 mM EDTA, pH 7.4. The cells are dispersed to a homogeneous suspension using a high shear mixer.

The cells are then lysed by passing the solution through a microfluidizer (Microfluidics, Corp. or APV Gaulin, Inc.) twice at 4000-6000 psi. The

homogenate is then mixed with NaCl solution to a final concentration of 0.5 M NaCl, followed by centrifugation at 7000 xg for 15 min. The resultant pellet is washed again using 0.5M NaCl, 100 mM Tris, 50 mM EDTA, pH 7.4.

The resulting washed inclusion bodies are solubilized with 1.5 M guanidine hydrochloride (GuHCl) for 2-4 hours. After 7000 xg centrifugation for 15 min., the pellet is discarded and the polypeptide containing supernatant is incubated at 4 degree C overnight to allow further GuHCl extraction.

Following high speed centrifugation (30,000 xg) to remove insoluble particles, the GuHCl solubilized protein is refolded by quickly mixing the GuHCl extract with 20 volumes of buffer containing 50 mM sodium, pH 4.5, 150 mM NaCl, 2 mM EDTA by vigorous stirring. The refolded diluted protein solution is kept at 4 degree C without mixing for 12 hours prior to further purification steps.

To clarify the refolded polypeptide solution, a previously prepared tangential filtration unit equipped with 0.16 um membrane filter with appropriate surface area (e.g., Filtron), equilibrated with 40 mM sodium acetate, pH 6.0 is employed. The filtered sample is loaded onto a cation exchange resin (e.g., Poros HS-50, Perseptive Biosystems). The column is washed with 40 mM sodium acetate, pH 6.0 and eluted with 250 mM, 500 mM, 1000 mM, and 1500 mM NaCl in the same buffer, in a stepwise manner. The absorbance at 280 nm of the effluent is continuously monitored. Fractions are collected and further analyzed by SDS-PAGE.

Fractions containing the METH1 or METH2 polypeptide are then pooled and mixed with 4 volumes of water. The diluted sample is then loaded onto a previously prepared set of tandem columns of strong anion (Poros HQ-50, Perseptive Biosystems) and weak anion (Poros CM-20, Perseptive Biosystems) exchange resins. The columns are equilibrated with 40 mM sodium acetate, pH 6.0. Both columns are washed with 40 mM sodium acetate, pH 6.0, 200 mM NaCl. The CM-20 column is then eluted using a 10 column volume linear gradient ranging from 0.2 M NaCl, 50 mM sodium acetate, pH 6.0 to 1.0 M NaCl, 50 mM sodium acetate, pH 6.5. Fractions are collected under constant A_{280} monitoring

-135-

of the effluent. Fractions containing the polypeptide (determined, for instance, by 16% SDS-PAGE) are then pooled.

The resultant METH1 or METH2 polypeptide should exhibit greater than 95% purity after the above refolding and purification steps. No major contaminant bands should be observed from Coomassie blue stained 16% SDS-PAGE gel when 5 ug of purified protein is loaded. The purified METH1 or METH2 protein can also be tested for endotoxin/LPS contamination, and typically the LPS content is less than 0.1 ng/ml according to LAL assays.

Example 9: Cloning and Expression of METH1 or METH2 in a Baculovirus Expression System

In this example, the plasmid shuttle vector pA2 is used to insert METH1 or METH2 polynucleotide into a baculovirus to express METH1 or METH2. This expression vector contains the strong polyhedrin promoter of the *Autographa californica* nuclear polyhedrosis virus (AcMNPV) followed by convenient restriction sites such as BamHI, Xba I and Asp718. The polyadenylation site of the simian virus 40 ("SV40") is used for efficient polyadenylation. For easy selection of recombinant virus, the plasmid contains the beta-galactosidase gene from *E. coli* under control of a weak *Drosophila* promoter in the same orientation, followed by the polyadenylation signal of the polyhedrin gene. The inserted genes are flanked on both sides by viral sequences for cell-mediated homologous recombination with wild-type viral DNA to generate a viable virus that express the cloned METH1 or METH2 polynucleotide.

Many other baculovirus vectors can be used in place of the vector above, such as pAc373, pVL941, and pAcIM1, as one skilled in the art would readily appreciate, as long as the construct provides appropriately located signals for transcription, translation, secretion and the like, including a signal peptide and an in-frame AUG as required. Such vectors are described, for instance, in Luckow et al., *Virology* 170:31-39 (1989).

Specifically, the METH1 or METH2 cDNA sequence contained in the deposited clone, including the AUG initiation codon and any naturally associated leader sequence, is amplified using the PCR protocol described in Example 5. If the naturally occurring signal sequence is used to produce the secreted protein, the pA2 vector does not need a second signal peptide. Alternatively, the vector can be modified (pA2 GP) to include a baculovirus leader sequence, using the standard methods described in Summers et al., "A Manual of Methods for Baculovirus Vectors and Insect Cell Culture Procedures," Texas Agricultural Experimental Station Bulletin No. 1555 (1987).

The amplified fragment is isolated from a 1% agarose gel using a commercially available kit ("GeneClean," BIO 101 Inc., La Jolla, Ca.). The fragment then is digested with appropriate restriction enzymes and again purified on a 1% agarose gel.

The plasmid is digested with the corresponding restriction enzymes and optionally, can be dephosphorylated using calf intestinal phosphatase, using routine procedures known in the art. The DNA is then isolated from a 1% agarose gel using a commercially available kit ("GeneClean" BIO 101 Inc., La Jolla, Ca.).

The fragment and the dephosphorylated plasmid are ligated together with T4 DNA ligase. *E. coli* HB101 or other suitable *E. coli* hosts such as XL-1 Blue (Stratagene Cloning Systems, La Jolla, CA) cells are transformed with the ligation mixture and spread on culture plates. Bacteria containing the plasmid are identified by digesting DNA from individual colonies and analyzing the digestion product by gel electrophoresis. The sequence of the cloned fragment is confirmed by DNA sequencing.

Five ug of a plasmid containing the polynucleotide is co-transfected with 1.0 ug of a commercially available linearized baculovirus DNA ("BaculoGold^a baculovirus DNA", Pharmingen, San Diego, CA), using the lipofection method described by Felgner et al., Proc. Natl. Acad. Sci. USA 84:7413-7417 (1987). One ug of BaculoGold^a virus DNA and 5 ug of the plasmid are mixed in a sterile

well of a microtiter plate containing 50 ul of serum-free Grace's medium (Life Technologies Inc., Gaithersburg, MD). Afterwards, 10 ul Lipofectin plus 90 ul Grace's medium are added, mixed and incubated for 15 minutes at room temperature. Then the transfection mixture is added drop-wise to Sf9 insect cells (ATCC CRL 1711) seeded in a 35 mm tissue culture plate with 1 ml Grace's medium without serum. The plate is then incubated for 5 hours at 27 degrees C. The transfection solution is then removed from the plate and 1 ml of Grace's insect medium supplemented with 10% fetal calf serum is added. Cultivation is then continued at 27 degrees C for four days.

After four days the supernatant is collected and a plaque assay is performed, as described by Summers and Smith, *supra*. An agarose gel with "Blue Gal" (Life Technologies Inc., Gaithersburg) is used to allow easy identification and isolation of gal-expressing clones, which produce blue-stained plaques. (A detailed description of a "plaque assay" of this type can also be found in the user's guide for insect cell culture and baculovirology distributed by Life Technologies Inc., Gaithersburg, page 9-10.) After appropriate incubation, blue stained plaques are picked with the tip of a micropipettor (e.g., Eppendorf). The agar containing the recombinant viruses is then resuspended in a microcentrifuge tube containing 200 ul of Grace's medium and the suspension containing the recombinant baculovirus is used to infect Sf9 cells seeded in 35 mm dishes. Four days later the supernatants of these culture dishes are harvested and then they are stored at 4 degree C.

To verify the expression of the polypeptide, Sf9 cells are grown in Grace's medium supplemented with 10% heat-inactivated FBS. The cells are infected with the recombinant baculovirus containing the polynucleotide at a multiplicity of infection ("MOI") of about 2. If radiolabeled proteins are desired, 6 hours later the medium is removed and is replaced with SF900 II medium minus methionine and cysteine (available from Life Technologies Inc., Rockville, MD). After 42 hours, 5 uCi of ^{35}S -methionine and 5 uCi ^{35}S -cysteine (available from Amersham) are added. The cells are further incubated for 16 hours and then are harvested by

centrifugation. The proteins in the supernatant as well as the intracellular proteins are analyzed by SDS-PAGE followed by autoradiography (if radiolabeled).

Microsequencing of the amino acid sequence of the amino terminus of purified protein may be used to determine the amino terminal sequence of the produced METH1 or METH2 protein.

Example 10: Expression of METH1 or METH2 in Mammalian Cells

METH1 or METH2 polypeptide can be expressed in a mammalian cell. A typical mammalian expression vector contains a promoter element, which mediates the initiation of transcription of mRNA, a protein coding sequence, and signals required for the termination of transcription and polyadenylation of the transcript. Additional elements include enhancers, Kozak sequences and intervening sequences flanked by donor and acceptor sites for RNA splicing. Highly efficient transcription is achieved with the early and late promoters from SV40, the long terminal repeats (LTRs) from Retroviruses, e.g., RSV, HTLV1, HIV1 and the early promoter of the cytomegalovirus (CMV). However, cellular elements can also be used (e.g., the human actin promoter).

Suitable expression vectors for use in practicing the present invention include, for example, vectors such as pSVL and pMSG (Pharmacia, Uppsala, Sweden), pRSVcat (ATCC 37152), pSV2DHFR (ATCC 37146), pBC12MI (ATCC 67109), pCMVSPORT 2.0, and pCMVSPORT 3.0. Mammalian host cells that could be used include, human Hela, 293, H9 and Jurkat cells, mouse NIH3T3 and C127 cells, Cos 1, Cos 7 and CV1, quail QC1-3 cells, mouse L cells and Chinese hamster ovary (CHO) cells.

Alternatively, METH1 or METH2 polypeptide can be expressed in stable cell lines containing the METH1 or METH2 polynucleotide integrated into a chromosome. The co-transfection with a selectable marker such as DHFR, gpt, neomycin, hygromycin allows the identification and isolation of the transfected cells.

-139-

The transfected METH1 or METH2 gene can also be amplified to express large amounts of the encoded protein. The DHFR (dihydrofolate reductase) marker is useful in developing cell lines that carry several hundred or even several thousand copies of the gene of interest. (See, e.g., Alt, F. W., *et al.*, *J. Biol. Chem.* 253:1357-1370 (1978); Hamlin, J. L. and Ma, C., *Biochem. et Biophys. Acta* 1097:107-143 (1990); Page, M. J. and Sydenham, M. A., *Biotechnology* 9:64-68 (1991).) Another useful selection marker is the enzyme glutamine synthase (GS) (Murphy *et al.*, *Biochem J.* 227:277-279 (1991); Bebbington *et al.*, *Bio/Technology* 10:169-175 (1992). Using these markers, the mammalian cells are grown in selective medium and the cells with the highest resistance are selected. These cell lines contain the amplified gene(s) integrated into a chromosome. Chinese hamster ovary (CHO) and NSO cells are often used for the production of proteins.

Derivatives of the plasmid pSV2-DHFR (ATCC Accession No. 37146), the expression vectors pC4 (ATCC Accession No. 209646) and pC6 (ATCC Accession No. 209647) contain the strong promoter (LTR) of the Rous Sarcoma Virus (Cullen *et al.*, *Molecular and Cellular Biology*, 438-447 (March, 1985)) plus a fragment of the CMV-enhancer (Boshart *et al.*, *Cell* 41:521-530 (1985).) Multiple cloning sites, e.g., with the restriction enzyme cleavage sites BamHI, XbaI and Asp718, facilitate the cloning of METH1 or METH2. The vectors also contain the 3' intron, the polyadenylation and termination signal of the rat preproinsulin gene, and the mouse DHFR gene under control of the SV40 early promoter.

If a naturally occurring signal sequence is used to produce a secreted protein, the vector does not need a second signal peptide. Alternatively, if a naturally occurring signal sequence is not used, the vector can be modified to include a heterologous signal sequence in an effort to secrete the protein from the cell. (See, e.g., WO 96/34891.)

The amplified fragment is then digested with the appropriate restriction enzyme and purified on a 1% agarose gel using a commercially available kit

("GeneClean," BIO 101 Inc., La Jolla, Ca.). The isolated fragment and the dephosphorylated vector are then ligated with T4 DNA ligase. *E. coli* HB101 or XL-1 Blue cells are then transformed and bacteria are identified that contain the fragment inserted into plasmid pC6 or pC4 using, for instance, restriction enzyme analysis.

Chinese hamster ovary cells lacking an active DHFR gene is used for transfection. Five μ g of the expression plasmid pC6 or pC4 is cotransfected with 0.5 μ g of the plasmid pSVneo using lipofectin (Felgner et al., *supra*). The plasmid pSV2-neo contains a dominant selectable marker, the *neo* gene from Tn5 encoding an enzyme that confers resistance to a group of antibiotics including G418. The cells are seeded in alpha minus MEM supplemented with 1 mg/ml G418. After 2 days, the cells are trypsinized and seeded in hybridoma cloning plates (Greiner, Germany) in alpha minus MEM supplemented with 10, 25, or 50 ng/ml of methotrexate plus 1 mg/ml G418. After about 10-14 days single clones are trypsinized and then seeded in 6-well petri dishes or 10 ml flasks using different concentrations of methotrexate (50 nM, 100 nM, 200 nM, 400 nM, 800 nM). Clones growing at the highest concentrations of methotrexate are then transferred to new 6-well plates containing even higher concentrations of methotrexate (1 μ M, 2 μ M, 5 μ M, 10 mM, 20 mM). The same procedure is repeated until clones are obtained which grow at a concentration of 100 - 200 μ M. Expression of METH1 or METH2 is analyzed, for instance, by SDS-PAGE and Western blot or by reversed phase HPLC analysis.

Example 11: Construction of N-Terminal and/or C-Terminal Deletion Mutants

The following general approach may be used to clone a N-terminal or C-terminal deletion METH1 or METH2 deletion mutant. Generally, two oligonucleotide primers of about 15-25 nucleotides are derived from the desired 5' and 3' positions of a polynucleotide of SEQ ID NO:1 or SEQ ID NO:3. The 5' and 3' positions of the primers are determined based on the desired METH1 or

METH2 polynucleotide fragment. An initiation and stop codon are added to the 5' and 3' primers respectively, if necessary, to express the METH1 or METH2 polypeptide fragment encoded by the polynucleotide fragment. Preferred METH1 or METH2 polynucleotide fragments are those encoding the N-terminal and C-terminal deletion mutants disclosed above in the "Polynucleotide and Polypeptide Fragments" section of the Specification.

Additional nucleotides containing restriction sites to facilitate cloning of the METH1 or METH2 polynucleotide fragment in a desired vector may also be added to the 5' and 3' primer sequences. The METH1 or METH2 polynucleotide fragment is amplified from genomic DNA or from the deposited cDNA clone using the appropriate PCR oligonucleotide primers and conditions discussed herein or known in the art. The METH1 or METH2 polypeptide fragments encoded by the METH1 or METH2 polynucleotide fragments of the present invention may be expressed and purified in the same general manner as the full length polypeptides, although routine modifications may be necessary due to the differences in chemical and physical properties between a particular fragment and full length polypeptide.

As a means of exemplifying but not limiting the present invention, the polynucleotide encoding the METH1 polypeptide fragment D-40 to S-950 or the METH2 polypeptide fragment L-20 to L-890 is amplified and cloned as follows: A 5' primer is generated comprising a restriction enzyme site followed by an initiation codon in frame with the polynucleotide sequence encoding the N-terminal portion of the polypeptide fragment beginning with D-40 or L-20, respectively. A complementary 3' primer is generated comprising a restriction enzyme site followed by a stop codon in frame with the polynucleotide sequence encoding C-terminal portion of the METH1 or METH2 polypeptide fragment ending with S-950 or L-890, respectively.

The amplified polynucleotide fragment and the expression vector are digested with restriction enzymes which recognize the sites in the primers. The digested polynucleotides are then ligated together. The METH1 or METH2

polynucleotide fragment is inserted into the restricted expression vector, preferably in a manner which places the METH1 or METH2 polypeptide fragment coding region downstream from the promoter. The ligation mixture is transformed into competent *E. coli* cells using standard procedures and as described in the Examples herein. Plasmid DNA is isolated from resistant colonies and the identity of the cloned DNA confirmed by restriction analysis, PCR and DNA sequencing.

Example 12: Protein Fusions of METH1 or METH2

METH1 or METH2 polypeptides are preferably fused to other proteins. These fusion proteins can be used for a variety of applications. For example, fusion of METH1 or METH2 polypeptides to His-tag, HA-tag, protein A, IgG domains, and maltose binding protein facilitates purification. (See Example 7; see also EP A 394,827; Traunecker, *et al.*, *Nature* 331:84-86 (1988).) Similarly, fusion to IgG-1, IgG-3, and albumin increases the halflife time in vivo. Nuclear localization signals fused to METH1 or METH2 polypeptides can target the protein to a specific subcellular localization, while covalent heterodimer or homodimers can increase or decrease the activity of a fusion protein. Fusion proteins can also create chimeric molecules having more than one function. Finally, fusion proteins can increase solubility and/or stability of the fused protein compared to the non-fused protein. All of the types of fusion proteins described above can be made by modifying the following protocol, which outlines the fusion of a polypeptide to an IgG molecule, or the protocol described in Example 7.

Briefly, the human Fc portion of the IgG molecule can be PCR amplified, using primers that span the 5' and 3' ends of the sequence described below. These primers also should have convenient restriction enzyme sites that will facilitate cloning into an expression vector, preferably a mammalian expression vector.

For example, if pC4 (Accession No. 209646) is used, the human Fc portion can be ligated into the BamHI cloning site. Note that the 3' BamHI site

-143-

should be destroyed. Next, the vector containing the human Fc portion is re-restricted with BamHI, linearizing the vector, and METH1 or METH2 polynucleotide, isolated by the PCR protocol described in Example 5, is ligated into this BamHI site. Note that the polynucleotide is cloned without a stop codon, otherwise a fusion protein will not be produced.

If the naturally occurring signal sequence is used to produce the secreted protein, pC4 does not need a second signal peptide. Alternatively, if the naturally occurring signal sequence is not used, the vector can be modified to include a heterologous signal sequence. (See, e.g., WO 96/34891.)

Example 13: Production of an Antibody

The antibodies of the present invention can be prepared by a variety of methods. (See, Current Protocols, Chapter 2.) For example, cells expressing METH1 or METH2 is administered to an animal to induce the production of sera containing polyclonal antibodies. In a preferred method, a preparation of METH1 or METH2 protein is prepared and purified to render it substantially free of natural contaminants. Such a preparation is then introduced into an animal in order to produce polyclonal antisera of greater specific activity.

In the most preferred method, the antibodies of the present invention are monoclonal antibodies (or protein binding fragments thereof). Such monoclonal antibodies can be prepared using hybridoma technology. (Kohler *et al.*, *Nature* 256:495 (1975); Kohler *et al.*, *Eur. J. Immunol.* 6:511 (1976); Kohler *et al.*, *Eur. J. Immunol.* 6:292 (1976); Hammerling *et al.*, in: *Monoclonal Antibodies and T-Cell Hybridomas*, Elsevier, N.Y., pp. 563-681 (1981).) In general, such procedures involve immunizing an animal (preferably a mouse) with METH1 or METH2 polypeptide or, more preferably, with a secreted METH1 or METH2 polypeptide-expressing cell. Such cells may be cultured in any suitable tissue culture medium; however, it is preferable to culture cells in Earle's modified Eagle's medium supplemented with 10% fetal bovine serum (inactivated at about 56 degree C), and supplemented with about 10 g/l of nonessential amino acids, about 1,000 U/ml of penicillin, and about 100 ug/ml of streptomycin.

The splenocytes of such mice are extracted and fused with a suitable myeloma cell line. Any suitable myeloma cell line may be employed in accordance with the present invention; however, it is preferable to employ the parent myeloma cell line (SP2O), available from the ATCC. After fusion, the resulting hybridoma cells are selectively maintained in HAT medium, and then cloned by limiting dilution as described by Wands *et al.* (*Gastroenterology* 80:225-232 (1981).) The hybridoma cells obtained through such a selection are then assayed to identify

clones which secrete antibodies capable of binding the METH1 or METH2 polypeptide.

Alternatively, additional antibodies capable of binding to METH1 or METH2 polypeptide can be produced in a two-step procedure using anti-idiotypic antibodies. Such a method makes use of the fact that antibodies are themselves antigens, and therefore, it is possible to obtain an antibody which binds to a second antibody. In accordance with this method, protein specific antibodies are used to immunize an animal, preferably a mouse. The splenocytes of such an animal are then used to produce hybridoma cells, and the hybridoma cells are screened to identify clones which produce an antibody whose ability to bind to the METH1 or METH2 protein-specific antibody can be blocked by METH1 or METH2. Such antibodies comprise anti-idiotypic antibodies to the METH1 or METH2 protein-specific antibody and can be used to immunize an animal to induce formation of further METH1 or METH2 protein-specific antibodies.

It will be appreciated that Fab and F(ab')₂ and other fragments of the antibodies of the present invention may be used according to the methods disclosed herein. Such fragments are typically produced by proteolytic cleavage, using enzymes such as papain (to produce Fab fragments) or pepsin (to produce F(ab')₂ fragments). Alternatively, secreted METH1 or METH2 protein-binding fragments can be produced through the application of recombinant DNA technology or through synthetic chemistry.

For in vivo use of antibodies in humans, it may be preferable to use "humanized" chimeric monoclonal antibodies. Such antibodies can be produced using genetic constructs derived from hybridoma cells producing the monoclonal antibodies described above. Methods for producing chimeric antibodies are known in the art. (See, for review, Morrison, *Science* 229:1202 (1985); Oi *et al.*, *BioTechniques* 4:214 (1986); Cabilly *et al.*, U.S. Patent No. 4,816,567; Taniguchi *et al.*, EP 171496; Morrison *et al.*, EP 173494; Neuberger *et al.*, WO 8601533; Robinson *et al.*, WO 8702671; Boulianne *et al.*, *Nature* 312:643 (1984); Neuberger *et al.*, *Nature* 314:268 (1985).)

Example 14: Production Of METH1 or METH2 Protein For High-Throughput Screening Assays

The following protocol produces a supernatant containing METH1 or METH2 polypeptide to be tested. This supernatant can then be used in the Screening Assays described in Examples 16-23.

First, dilute Poly-D-Lysine (644 587 Boehringer-Mannheim) stock solution (1mg/ml in PBS) 1:20 in PBS (w/o calcium or magnesium 17-516F Biowhittaker) for a working solution of 50ug/ml. Add 200 ul of this solution to each well (24 well plates) and incubate at RT for 20 minutes. Be sure to distribute the solution over each well (note: a 12-channel pipetter may be used with tips on every other channel). Aspirate off the Poly-D-Lysine solution and rinse with 1ml PBS (Phosphate Buffered Saline). The PBS should remain in the well until just prior to plating the cells and plates may be poly-lysine coated in advance for up to two weeks.

Plate 293T cells (do not carry cells past P+20) at 2×10^5 cells/well in .5ml DMEM(Dulbecco's Modified Eagle Medium)(with 4.5 G/L glucose and L-glutamine (12-604F Biowhittaker))/10% heat inactivated FBS(14-503F Biowhittaker)/1x Penstrep(17-602E Biowhittaker). Let the cells grow overnight.

The next day, mix together in a sterile solution basin: 300 ul Lipofectamine (18324-012 Gibco/BRL) and 5ml Optimem I (31985070 Gibco/BRL)/96-well plate. With a small volume multi-channel pipetter, aliquot approximately 2ug of an expression vector containing a polynucleotide insert, produced by the methods described in Examples 10-12, into an appropriately labeled 96-well round bottom plate. With a multi-channel pipetter, add 50ul of the Lipofectamine/Optimem I mixture to each well. Pipette up and down gently to mix. Incubate at RT 15-45 minutes. After about 20 minutes, use a multi-channel pipetter to add 150ul Optimem I to each well. As a control, one plate of vector DNA lacking an insert should be transfected with each set of transfections.

Preferably, the transfection should be performed by tag-teaming the following tasks. By tag-teaming, hands on time is cut in half, and the cells do not

spend too much time on PBS. First, person A aspirates off the media from four 24-well plates of cells, and then person B rinses each well with .5-1ml PBS. Person A then aspirates off PBS rinse, and person B, using a 12-channel pipetter with tips on every other channel, adds the 200ul of DNA/Lipofectamine/Optimem I complex to the odd wells first, then to the even wells, to each row on the 24-well plates. Incubate at 37 degree C for 6 hours.

While cells are incubating, prepare appropriate media, either 1%BSA in DMEM with 1x penstrep, or HGS CHO-5 media (116.6 mg/L of CaCl_2 (anhyd); 0.00130 mg/L $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$; 0.050 mg/L of $\text{Fe}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$; 0.417 mg/L of $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$; 311.80 mg/L of KCl; 28.64 mg/L of MgCl_2 ; 48.84 mg/L of MgSO_4 ; 6995.50 mg/L of NaCl; 2400.0 mg/L of NaHCO_3 ; 62.50 mg/L of $\text{NaH}_2\text{PO}_4 \cdot \text{H}_2\text{O}$; 71.02 mg/L of Na_2HPO_4 ; .4320 mg/L of $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$; .002 mg/L of Arachidonic Acid; 1.022 mg/L of Cholesterol; .070 mg/L of DL-alpha-Tocopherol-Acetate; 0.0520 mg/L of Linoleic Acid; 0.010 mg/L of Linolenic Acid; 0.010 mg/L of Myristic Acid; 0.010 mg/L of Oleic Acid; 0.010 mg/L of Palmitric Acid; 0.010 mg/L of Palmitic Acid; 100 mg/L of Pluronic F-68; 0.010 mg/L of Stearic Acid; 2.20 mg/L of Tween 80; 4551 mg/L of D-Glucose; 130.85 mg/ml of L- Alanine; 147.50 mg/ml of L-Arginine-HCL; 7.50 mg/ml of L-Asparagine- H_2O ; 6.65 mg/ml of L-Aspartic Acid; 29.56 mg/ml of L-Cystine-2HCL- H_2O ; 31.29 mg/ml of L-Cystine-2HCL; 7.35 mg/ml of L-Glutamic Acid; 365.0 mg/ml of L-Glutamine; 18.75 mg/ml of Glycine; 52.48 mg/ml of L-Histidine-HCL- H_2O ; 106.97 mg/ml of L-Isoleucine; 111.45 mg/ml of L-Leucine; 163.75 mg/ml of L-Lysine HCL; 32.34 mg/ml of L-Methionine; 68.48 mg/ml of L-Phenylalanine; 40.0 mg/ml of L-Proline; 26.25 mg/ml of L-Serine; 101.05 mg/ml of L-Threonine; 19.22 mg/ml of L-Tryptophan; 91.79 mg/ml of L-Tyrosine-2Na- $2\text{H}_2\text{O}$; and 99.65 mg/ml of L-Valine; 0.0035 mg/L of Biotin; 3.24 mg/L of D-Ca Pantothenate; 11.78 mg/L of Choline Chloride; 4.65 mg/L of Folic Acid; 15.60 mg/L of i-Inositol; 3.02 mg/L of Niacinamide; 3.00 mg/L of Pyridoxal HCL; 0.031 mg/L of Pyridoxine HCL; 0.319 mg/L of Riboflavin; 3.17 mg/L of Thiamine HCL; 0.365 mg/L of Thymidine; 0.680 mg/L of Vitamin B₁₂; 25 mM of HEPES Buffer; 2.39 mg/L of

Na Hypoxanthine; 0.105 mg/L of Lipoic Acid; 0.081 mg/L of Sodium Putrescine-2HCL; 55.0 mg/L of Sodium Pyruvate; 0.0067 mg/L of Sodium Selenite; 20uM of Ethanolamine; 0.122 mg/L of Ferric Citrate; 41.70 mg/L of Methyl-B-Cyclodextrin complexed with Linoleic Acid; 33.33 mg/L of Methyl-B-Cyclodextrin complexed with Oleic Acid; 10 mg/L of Methyl-B-Cyclodextrin complexed with Retinal Acetate. Adjust osmolarity to 327 mOsm) with 2mm glutamine and 1x penstrep. (BSA (81-068-3 Bayer) 100gm dissolved in 1L DMEM for a 10% BSA stock solution). Filter the media and collect 50 ul for endotoxin assay in 15ml polystyrene conical.

The transfection reaction is terminated, preferably by tag-teaming, at the end of the incubation period. Person A aspirates off the transfection media, while person B adds 1.5ml appropriate media to each well. Incubate at 37 degree C for 45 or 72 hours depending on the media used: 1%BSA for 45 hours or CHO-5 for 72 hours.

On day four, using a 300ul multichannel pipetter, aliquot 600ul in one 1ml deep well plate and the remaining supernatant into a 2ml deep well. The supernatants from each well can then be used in the assays described in Examples 16-23.

It is specifically understood that when activity is obtained in any of the assays described below using a supernatant, the activity originates from either the METH1 or METH2 polypeptide directly (e.g., as a secreted protein) or by METH1 or METH2 inducing expression of other proteins, which are then secreted into the supernatant. Thus, the invention further provides a method of identifying the protein in the supernatant characterized by an activity in a particular assay.

Example 15: Construction of GAS Reporter Construct

One signal transduction pathway involved in the differentiation and proliferation of cells is called the Jaks-STATs pathway. Activated proteins in the

Jaks-STATs pathway bind to gamma activation site "GAS" elements or interferon-sensitive responsive element ("ISRE"), located in the promoter of many genes. The binding of a protein to these elements alter the expression of the associated gene.

5 GAS and ISRE elements are recognized by a class of transcription factors called Signal Transducers and Activators of Transcription, or "STATs." There are six members of the STATs family. Stat1 and Stat3 are present in many cell types, as is Stat2 (as response to IFN-alpha is widespread). Stat4 is more restricted and is not in many cell types though it has been found in T helper class I, cells after
10 treatment with IL-12. Stat5 was originally called mammary growth factor, but has been found at higher concentrations in other cells including myeloid cells. It can be activated in tissue culture cells by many cytokines.

 The STATs are activated to translocate from the cytoplasm to the nucleus upon tyrosine phosphorylation by a set of kinases known as the Janus Kinase
15 ("Jaks") family. Jaks represent a distinct family of soluble tyrosine kinases and include Tyk2, Jak1, Jak2, and Jak3. These kinases display significant sequence similarity and are generally catalytically inactive in resting cells.

 The Jaks are activated by a wide range of receptors summarized in the Table below. (Adapted from review by Schidler and Darnell, *Ann. Rev. Biochem.*
20 64:621-51 (1995).) A cytokine receptor family, capable of activating Jaks, is divided into two groups: (a) Class 1 includes receptors for IL-2, IL-3, IL-4, IL-6, IL-7, IL-9, IL-11, IL-12, IL-15, Epo, PRL, GH, G-CSF, GM-CSF, LIF, CNTF, and thrombopoietin; and (b) Class 2 includes IFN-a, IFN-g, and IL-10. The Class 1 receptors share a conserved cysteine motif (a set of four conserved cysteines and one tryptophan) and a WSXWS motif (a membrane proximal region encoding Trp-Ser-Xxx-Trp-Ser (SEQ ID NO:82)).
25

 Thus, on binding of a ligand to a receptor, Jaks are activated, which in turn activate STATs, which then translocate and bind to GAS elements. This entire process is encompassed in the Jaks-STATs signal transduction pathway.

-150-

Therefore, activation of the Jaks-STATs pathway, reflected by the binding of the GAS or the ISRE element, can be used to indicate proteins involved in the proliferation and differentiation of cells. For example, growth factors and cytokines are known to activate the Jaks-STATs pathway. (See Table below.)

Thus, by using GAS elements linked to reporter molecules, activators of the Jaks-STATs pathway can be identified.

	JAKs				STATS	GAS(elements) or ISRE

-151-

To construct a synthetic GAS containing promoter element, which is used in the Biological Assays described in Examples 16-17, a PCR based strategy is employed to generate a GAS-SV40 promoter sequence. The 5' primer contains four tandem copies of the GAS binding site found in the IRF1 promoter and previously demonstrated to bind STATs upon induction with a range of cytokines (Rothman *et al.*, *Immunity* 1:457-468 (1994).), although other GAS or ISRE elements can be used instead. The 5' primer also contains 18bp of sequence complementary to the SV40 early promoter sequence and is flanked with an XhoI site. The sequence of the 5' primer is:

5':GCGCCTCGAGATTTCCCGAAATCTAGATTTCCCGAAATGATTT
CCCGAAATGATTTCCCGAAATATCTGCCATCTCAATTAG:3' (SEQ ID
NO:86)

The downstream primer is complementary to the SV40 promoter and is flanked with a Hind III site: 5':GCGGCAAGCTTTTGTCAAAGCCTAGGC:3' (SEQ ID NO:87)

PCR amplification is performed using the SV40 promoter template present in the B-gal:promoter plasmid obtained from Clontech. The resulting PCR fragment is digested with XhoI/Hind III and subcloned into BLSK2-. (Stratagene.) Sequencing with forward and reverse primers confirms that the insert contains the following sequence:

5':CTCGAGATTTCCCGAAATCTAGATTTCCCGAAATGATTTCCCG
GAAATGATTTCCCGAAATATCTGCCATCTCAATTAGTCAGCAACCA
TAGTCCCGCCCCCTAACTCCGCCCATCCCGCCCCTAACTCCGCCCAGT
TCCGCCCATTCTCCGCCCCATGGCTGACTAATTTTTTTTATTTATGCA
GAGGCCGAGGCCGCCTCGGCCTCTGAGCTATTCCAGAAGTAGTGAG
GAGGCTTTTTTGGAGGCCTAGGCTTTTGCAAAAAGCTT:3' (SEQ ID
NO:88)

With this GAS promoter element linked to the SV40 promoter, a GAS:SEAP2 reporter construct is next engineered. Here, the reporter molecule is a secreted alkaline phosphatase, or "SEAP." Clearly, however, any reporter

-152-

molecule can be instead of SEAP, in this or in any of the other Examples. Well known reporter molecules that can be used instead of SEAP include chloramphenicol acetyltransferase (CAT), luciferase, alkaline phosphatase, B-galactosidase, green fluorescent protein (GFP), or any protein detectable by an antibody.

The above sequence confirmed synthetic GAS-SV40 promoter element is subcloned into the pSEAP-Promoter vector obtained from Clontech using HindIII and XhoI, effectively replacing the SV40 promoter with the amplified GAS:SV40 promoter element, to create the GAS-SEAP vector. However, this vector does not contain a neomycin resistance gene, and therefore, is not preferred for mammalian expression systems.

Thus, in order to generate mammalian stable cell lines expressing the GAS-SEAP reporter, the GAS-SEAP cassette is removed from the GAS-SEAP vector using SalI and NotI, and inserted into a backbone vector containing the neomycin resistance gene, such as pGFP-1 (Clontech), using these restriction sites in the multiple cloning site, to create the GAS-SEAP/Neo vector. Once this vector is transfected into mammalian cells, this vector can then be used as a reporter molecule for GAS binding as described in Examples 16-17.

Other constructs can be made using the above description and replacing GAS with a different promoter sequence. For example, construction of reporter molecules containing NFK-B and EGR promoter sequences are described in Examples 18 and 19. However, many other promoters can be substituted using the protocols described in these Examples. For instance, SRE, IL-2, NFAT, or Osteocalcin promoters can be substituted, alone or in combination (e.g., GAS/NF-KB/EGR, GAS/NF-KB, IL-2/NFAT, or NF-KB/GAS). Similarly, other cell lines can be used to test reporter construct activity, such as HELA (epithelial), HUVEC (endothelial), Reh (B-cell), Saos-2 (osteoblast), HUVAC (aortic), or Cardiomyocyte.

-153-

Example 16: High-Throughput Screening Assay for T-cell Activity

The following protocol is used to assess T-cell activity of METH1 or METH2 by determining whether METH1 or METH2 supernatant proliferates and/or differentiates T-cells. T-cell activity is assessed using the GAS/SEAP/Neo construct produced in Example 15. Thus, factors that increase SEAP activity indicate the ability to activate the Jaks-STATS signal transduction pathway. The T-cell used in this assay is Jurkat T-cells (ATCC Accession No. TIB-152), although Molt-3 cells (ATCC Accession No. CRL-1552) and Molt-4 cells (ATCC Accession No. CRL-1582) cells can also be used.

Jurkat T-cells are lymphoblastic CD4⁺ Th1 helper cells. In order to generate stable cell lines, approximately 2 million Jurkat cells are transfected with the GAS-SEAP/neo vector using DMRIE-C (Life Technologies)(transfection procedure described below). The transfected cells are seeded to a density of approximately 20,000 cells per well and transfectants resistant to 1 mg/ml gentamicin selected. Resistant colonies are expanded and then tested for their response to increasing concentrations of interferon gamma. The dose response of a selected clone is demonstrated.

Specifically, the following protocol will yield sufficient cells for 75 wells containing 200 ul of cells. Thus, it is either scaled up, or performed in multiple to generate sufficient cells for multiple 96 well plates. Jurkat cells are maintained in RPMI + 10% serum with 1%Pen-Strep. Combine 2.5 mls of OPTI-MEM (Life Technologies) with 10 ug of plasmid DNA in a T25 flask. Add 2.5 ml OPTI-MEM containing 50 ul of DMRIE-C and incubate at room temperature for 15-45 mins.

During the incubation period, count cell concentration, spin down the required number of cells (10^7 per transfection), and resuspend in OPTI-MEM to a final concentration of 10^7 cells/ml. Then add 1 ml of 1×10^7 cells in OPTI-MEM to T25 flask and incubate at 37 degree C for 6 hrs. After the incubation, add 10 ml of RPMI + 15% serum.

-154-

The Jurkat:GAS-SEAP stable reporter lines are maintained in RPMI + 10% serum, 1 mg/ml Gentamicin, and 1% Pen-Strep. These cells are treated with supernatants containing METH1 or METH2 polypeptides or METH1 or METH2 induced polypeptides as produced by the protocol described in Example 14.

5 On the day of treatment with the supernatant, the cells should be washed and resuspended in fresh RPMI + 10% serum to a density of 500,000 cells per ml. The exact number of cells required will depend on the number of supernatants being screened. For one 96 well plate, approximately 10 million cells (for 10 plates, 100 million cells) are required.

10 Transfer the cells to a triangular reservoir boat, in order to dispense the cells into a 96 well dish, using a 12 channel pipette. Using a 12 channel pipette, transfer 200 ul of cells into each well (therefore adding 100,000 cells per well).

After all the plates have been seeded, 50 ul of the supernatants are transferred directly from the 96 well plate containing the supernatants into each well using a 12 channel pipette. In addition, a dose of exogenous interferon gamma (0.1, 1.0, 10 ng) is added to wells H9, H10, and H11 to serve as additional positive controls for the assay.

15 The 96 well dishes containing Jurkat cells treated with supernatants are placed in an incubator for 48 hrs (note: this time is variable between 48-72 hrs). 35 ul samples from each well are then transferred to an opaque 96 well plate using a 12 channel pipette. The opaque plates should be covered (using sellophene covers) and stored at -20 degree C until SEAP assays are performed according to Example 20. The plates containing the remaining treated cells are placed at 4 degree C and serve as a source of material for repeating the assay on a specific well if desired.

25 As a positive control, 100 Unit/ml interferon gamma can be used which is known to activate Jurkat T cells. Over 30 fold induction is typically observed in the positive control wells.

-155-

Example 17: High-Throughput Screening Assay Identifying Myeloid Activity

The following protocol is used to assess myeloid activity of METH1 or METH2 by determining whether METH1 or METH2 proliferates and/or differentiates myeloid cells. Myeloid cell activity is assessed using the GAS/SEAP/Neo construct produced in Example 15. Thus, factors that increase SEAP activity indicate the ability to activate the Jaks-STATS signal transduction pathway. The myeloid cell used in this assay is U937, a pre-monocyte cell line, although TF-1, HL60, or KG1 can be used.

To transiently transfect U937 cells with the GAS/SEAP/Neo construct produced in Example 15, a DEAE-Dextran method (Kharbanda *et. al.*, 1994, *Cell Growth & Differentiation* 5:259-265) is used. First, harvest 2×10^7 U937 cells and wash with PBS. The U937 cells are usually grown in RPMI 1640 medium containing 10% heat-inactivated fetal bovine serum (FBS) supplemented with 100 units/ml penicillin and 100 mg/ml streptomycin.

Next, suspend the cells in 1 ml of 20 mM Tris-HCl (pH 7.4) buffer containing 0.5 mg/ml DEAE-Dextran, 8 ug GAS-SEAP2 plasmid DNA, 140 mM NaCl, 5 mM KCl, 375 uM $\text{Na}_2\text{HPO}_4 \cdot 7\text{H}_2\text{O}$, 1 mM MgCl_2 , and 675 uM CaCl_2 . Incubate at 37 degree C for 45 min.

Wash the cells with RPMI 1640 medium containing 10% FBS and then resuspend in 10 ml complete medium and incubate at 37 degree C for 36 hr.

The GAS-SEAP/U937 stable cells are obtained by growing the cells in 400 ug/ml G418. The G418-free medium is used for routine growth but every one to two months, the cells should be re-grown in 400 ug/ml G418 for couple of passages.

These cells are tested by harvesting 1×10^6 cells (this is enough for ten 96-well plates assay) and wash with PBS. Suspend the cells in 200 ml above described growth medium, with a final density of 5×10^5 cells/ml. Plate 200 ul cells per well in the 96-well plate (or 1×10^5 cells/well).

-156-

Add 50 ul of the supernatant prepared by the protocol described in Example 14. Incubate at 37 degree C for 48 to 72 hr. As a positive control, 100 Unit/ml interferon gamma can be used which is known to activate U937 cells. Over 30 fold induction is typically observed in the positive control wells. SEAP assay the supernatant according to the protocol described in Example 20.

Example 18: High-Throughput Screening Assay Identifying Neuronal Activity

When cells undergo differentiation and proliferation, a group of genes are activated through many different signal transduction pathways. One of these genes, EGR1 (early growth response gene 1), is induced in various tissues and cell types upon activation. The promoter of EGR1 is responsible for such induction. Using the EGR1 promoter linked to reporter molecules, activation of cells can be assessed by METH1 or METH2.

Particularly, the following protocol is used to assess neuronal activity in PC12 cell lines. PC12 cells (rat phenochromocytoma cells) are known to proliferate and/or differentiate by activation with a number of mitogens, such as TPA (tetradecanoyl phorbol acetate), NGF (nerve growth factor), and EGF (epidermal growth factor). The EGR1 gene expression is activated during this treatment. Thus, by stably transfecting PC12 cells with a construct containing an EGR promoter linked to SEAP reporter, activation of PC12 cells by METH1 or METH2 can be assessed.

The EGR/SEAP reporter construct can be assembled by the following protocol. The EGR-1 promoter sequence (-633 to +1)(Sakamoto K *et al.*, *Oncogene* 6:867-871 (1991)) can be PCR amplified from human genomic DNA using the following primers:

5' GCGCTCGAGGGATGACAGCGATAGAACCCCGG -3' (SEQ ID NO:89)

5' GCGAAGCTTCGCGACTCCCCGGATCCGCCTC-3' (SEQ ID NO:90)

-157-

Using the GAS:SEAP/Neo vector produced in Example 15, EGR1 amplified product can then be inserted into this vector. Linearize the GAS:SEAP/Neo vector using restriction enzymes XhoI/HindIII, removing the GAS/SV40 stuffer. Restrict the EGR1 amplified product with these same enzymes. Ligate the vector and the EGR1 promoter.

To prepare 96 well-plates for cell culture, two mls of a coating solution (1:30 dilution of collagen type I (Upstate Biotech Inc. Cat#08-115) in 30% ethanol (filter sterilized)) is added per one 10 cm plate or 50 ml per well of the 96-well plate, and allowed to air dry for 2 hr.

PC12 cells are routinely grown in RPMI-1640 medium (Bio Whittaker) containing 10% horse serum (JRH BIOSCIENCES, Cat. # 12449-78P), 5% heat-inactivated fetal bovine serum (FBS) supplemented with 100 units/ml penicillin and 100 ug/ml streptomycin on a precoated 10 cm tissue culture dish. One to four split is done every three to four days. Cells are removed from the plates by scraping and resuspended with pipetting up and down for more than 15 times.

Transfect the EGR/SEAP/Neo construct into PC12 using the Lipofectamine protocol described in Example 14. EGR-SEAP/PC12 stable cells are obtained by growing the cells in 300 ug/ml G418. The G418-free medium is used for routine growth but every one to two months, the cells should be re-grown in 300 ug/ml G418 for couple of passages.

To assay for neuronal activity, a 10 cm plate with cells around 70 to 80% confluent is screened by removing the old medium. Wash the cells once with PBS (Phosphate buffered saline). Then starve the cells in low serum medium (RPMI-1640 containing 1% horse serum and 0.5% FBS with antibiotics) overnight.

The next morning, remove the medium and wash the cells with PBS. Scrape off the cells from the plate, suspend the cells well in 2 ml low serum medium. Count the cell number and add more low serum medium to reach final cell density as 5×10^5 cells/ml.

Add 200 ul of the cell suspension to each well of 96-well plate (equivalent to 1×10^5 cells/well). Add 50 ul supernatant produced by Example 14, 37 degree

-158-

C for 48 to 72 hr. As a positive control, a growth factor known to activate PC12 cells through EGR can be used, such as 50 ng/ul of Neuronal Growth Factor (NGF). Over fifty-fold induction of SEAP is typically seen in the positive control wells. SEAP assay the supernatant according to Example 20.

5 ***Example 19: High-Throughput Screening Assay for T-cell Activity***

10 NF- κ B (Nuclear Factor κ B) is a transcription factor activated by a wide variety of agents including the inflammatory cytokines IL-1 and TNF, CD30 and CD40, lymphotoxin-alpha and lymphotoxin-beta, by exposure to LPS or thrombin, and by expression of certain viral gene products. As a transcription factor, NF- κ B regulates the expression of genes involved in immune cell activation, control of apoptosis (NF- κ B appears to shield cells from apoptosis), B and T-cell development, anti-viral and antimicrobial responses, and multiple stress responses.

15 In non-stimulated conditions, NF- κ B is retained in the cytoplasm with I- κ B (Inhibitor κ B). However, upon stimulation, I- κ B is phosphorylated and degraded, causing NF- κ B to shuttle to the nucleus, thereby activating transcription of target genes. Target genes activated by NF- κ B include IL-2, IL-6, GM-CSF, ICAM-1 and class I MHC.

20 Due to its central role and ability to respond to a range of stimuli, reporter constructs utilizing the NF- κ B promoter element are used to screen the supernatants produced in Example 14. Activators or inhibitors of NF- κ B would be useful in treating diseases. For example, inhibitors of NF- κ B could be used to treat those diseases related to the acute or chronic activation of NF- κ B, such as rheumatoid arthritis.

25 To construct a vector containing the NF- κ B promoter element, a PCR based strategy is employed. The upstream primer contains four tandem copies of the NF- κ B binding site (GGGGACTTCCCC) (SEQ ID NO:91), 18 bp of sequence complementary to the 5' end of the SV40 early promoter sequence, and is flanked with an XhoI site:

-159-

5':GCGGCCTCGAGGGGACTTTCCCGGGGACTTTCCGGGGACTTTCCG
GGACTTTCCATCCTGCCATCTCAATTAG:3' (SEQ ID NO:92)

The downstream primer is complementary to the 3' end of the SV40 promoter and is flanked with a Hind III site:

5 5':GCGGCAAGCTTTTTGCAAAGCCTAGGC:3' (SEQ ID NO:93)

PCR amplification is performed using the SV40 promoter template present in the pB-gal:promoter plasmid obtained from Clontech. The resulting PCR fragment is digested with XhoI and Hind III and subcloned into BLSK2- (Stratagene) Sequencing with the T7 and T3 primers confirms the insert contains the following sequence:

5':CTCGAGGGGACTTTCCCGGGGACTTTCCGGGGACTTTCCGGGACT
TTCCATCTGCCATCTCAATTAGTCAGCAACCATAGTCCCGCCCCTAA
CTCCGCCCATCCCGCCCCTAACTCCGCCCAGTTCCGCCCATTCTCCG
CCCCATGGCTGACTAATTTTTTTTATTTATGCAGAGGCCGAGGCCGC
15 CTCGGCCTCTGAGCTATTCCAGAAGTAGTGAGGAGGCTTTTTTGGAG
GGCCTAGGCTTTTGCAAAAAGCTT:3' (SEQ ID NO:88)

Next, replace the SV40 minimal promoter element present in the pSEAP2-promoter plasmid (Clontech) with this NF-KB/SV40 fragment using XhoI and HindIII. However, this vector does not contain a neomycin resistance gene, and therefore, is not preferred for mammalian expression systems.

In order to generate stable mammalian cell lines, the NF-KB/SV40/SEAP cassette is removed from the above NF-KB/SEAP vector using restriction enzymes SalI and NotI, and inserted into a vector containing neomycin resistance. Particularly, the NF-KB/SV40/SEAP cassette was inserted into pGFP-1 (Clontech), replacing the GFP gene, after restricting pGFP-1 with SalI and NotI.

25 Once NF-KB/SV40/SEAP/Neo vector is created, stable Jurkat T-cells are created and maintained according to the protocol described in Example 16. Similarly, the method for assaying supernatants with these stable Jurkat T-cells is also described in Example 16. As a positive control, exogenous TNF alpha (0.1, 1,

-160-

10 ng) is added to wells H9, H10, and H11, with a 5-10 fold activation typically observed.

Example 20: Assay for SEAP Activity

As a reporter molecule for the assays described in Examples 16-19, SEAP activity is assayed using the Tropix Phospho-light Kit (Cat. BP-400) according to the following general procedure. The Tropix Phospho-light Kit supplies the Dilution, Assay, and Reaction Buffers used below.

Prime a dispenser with the 2.5x Dilution Buffer and dispense 15 ul of 2.5x dilution buffer into Optiplates containing 35 ul of a supernatant. Seal the plates with a plastic sealer and incubate at 65 degree C for 30 min. Separate the Optiplates to avoid uneven heating.

Cool the samples to room temperature for 15 minutes. Empty the dispenser and prime with the Assay Buffer. Add 50 ml Assay Buffer and incubate at room temperature 5 min. Empty the dispenser and prime with the Reaction Buffer (see the table below). Add 50 ul Reaction Buffer and incubate at room temperature for 20 minutes. Since the intensity of the chemiluminescent signal is time dependent, and it takes about 10 minutes to read 5 plates on luminometer, one should treat 5 plates at each time and start the second set 10 minutes later.

Read the relative light unit in the luminometer. Set H12 as blank, and print the results. An increase in chemiluminescence indicates reporter activity.

Reaction Buffer Formulation:

# of plates	Rxn buffer diluent (ml)	CSPD (ml)
10	60	3
11	65	3.25

Example 21: High-Throughput Screening Assay Identifying Changes in Small Molecule Concentration and Membrane Permeability

35 Binding of a ligand to a receptor is known to alter intracellular levels of small molecules, such as calcium, potassium, sodium, and pH, as well as alter membrane potential. These alterations can be measured in an assay to identify supernatants which bind to receptors of a particular cell. Although the following protocol describes an assay for calcium, this protocol can easily be modified to

-162-

detect changes in potassium, sodium, pH, membrane potential, or any other small molecule which is detectable by a fluorescent probe.

The following assay uses Fluorometric Imaging Plate Reader ("FLIPR") to measure changes in fluorescent molecules (Molecular Probes) that bind small molecules. Clearly, any fluorescent molecule detecting a small molecule can be used instead of the calcium fluorescent molecule, fluo-3, used here.

For adherent cells, seed the cells at 10,000 -20,000 cells/well in a Co-star black 96-well plate with clear bottom. The plate is incubated in a CO₂ incubator for 20 hours. The adherent cells are washed two times in Biotek washer with 200 ul of HBSS (Hank's Balanced Salt Solution) leaving 100 ul of buffer after the final wash.

A stock solution of 1 mg/ml fluo-3 is made in 10% pluronic acid DMSO. To load the cells with fluo-3, 50 ul of 12 ug/ml fluo-3 is added to each well. The plate is incubated at 37 degree C in a CO₂ incubator for 60 min. The plate is washed four times in the Biotek washer with HBSS leaving 100 ul of buffer.

For non-adherent cells, the cells are spun down from culture media. Cells are re-suspended to $2-5 \times 10^6$ cells/ml with HBSS in a 50-ml conical tube. 4 ul of 1 mg/ml fluo-3 solution in 10% pluronic acid DMSO is added to each ml of cell suspension. The tube is then placed in a 37 degree C water bath for 30-60 min. The cells are washed twice with HBSS, resuspended to 1×10^6 cells/ml, and dispensed into a microplate, 100 ul/well. The plate is centrifuged at 1000 rpm for 5 min. The plate is then washed once in Denley CellWash with 200 ul, followed by an aspiration step to 100 ul final volume.

For a non-cell based assay, each well contains a fluorescent molecule, such as fluo-3. The supernatant is added to the well, and a change in fluorescence is detected.

To measure the fluorescence of intracellular calcium, the FLIPR is set for the following parameters: (1) System gain is 300-800 mW; (2) Exposure time is 0.4 second; (3) Camera F/stop is F/2; (4) Excitation is 488 nm; (5) Emission is 530 nm; and (6) Sample addition is 50 ul. Increased emission at 530 nm indicates

-163-

an extracellular signaling event caused by the a molecule, either METH1 or METH2 or a molecule induced by METH1 or METH2, which has resulted in an increase in the intracellular Ca^{++} concentration.

5 ***Example 22: High-Throughput Screening Assay Identifying Tyrosine Kinase Activity***

The Protein Tyrosine Kinases (PTK) represent a diverse group of transmembrane and cytoplasmic kinases. Within the Receptor Protein Tyrosine Kinase (RPTK) group are receptors for a range of mitogenic and metabolic growth factors including the PDGF, FGF, EGF, NGF, HGF and Insulin receptor subfamilies. In addition there are a large family of RPTKs for which the
10 corresponding ligand is unknown. Ligands for RPTKs include mainly secreted small proteins, but also membrane-bound and extracellular matrix proteins.

Activation of RPTK by ligands involves ligand-mediated receptor dimerization, resulting in transphosphorylation of the receptor subunits and
15 activation of the cytoplasmic tyrosine kinases. The cytoplasmic tyrosine kinases include receptor associated tyrosine kinases of the src-family (e.g., src, yes, lck, lyn, fyn) and non-receptor linked and cytosolic protein tyrosine kinases, such as the Jak family, members of which mediate signal transduction triggered by the cytokine superfamily of receptors (e.g., the Interleukins, Interferons, GM-CSF,
20 and Leptin).

Because of the wide range of known factors capable of stimulating tyrosine kinase activity, identifying whether METH1 or METH2 or a molecule induced by METH1 or METH2 is capable of activating tyrosine kinase signal transduction pathways is of interest. Therefore, the following protocol is designed to identify
25 such molecules capable of activating the tyrosine kinase signal transduction pathways.

Seed target cells (e.g., primary keratinocytes) at a density of approximately 25,000 cells per well in a 96 well Loprodyne Silent Screen Plates purchased from Nalge Nunc (Naperville, IL). The plates are sterilized with two 30 minute rinses

-164-

with 100% ethanol, rinsed with water and dried overnight. Some plates are coated for 2 hr with 100 ml of cell culture grade type I collagen (50 mg/ml), gelatin (2%) or polylysine (50 mg/ml), all of which can be purchased from Sigma Chemicals (St. Louis, MO) or 10% Matrigel purchased from Becton Dickinson (Bedford, MA), or calf serum, rinsed with PBS and stored at 4 degree C. Cell growth on these plates is assayed by seeding 5,000 cells/well in growth medium and indirect quantitation of cell number through use of alamarBlue as described by the manufacturer Alamar Biosciences, Inc. (Sacramento, CA) after 48 hr. Falcon plate covers #3071 from Becton Dickinson (Bedford, MA) are used to cover the Loprodyne Silent Screen Plates. Falcon Microtest III cell culture plates can also be used in some proliferation experiments.

To prepare extracts, A431 cells are seeded onto the nylon membranes of Loprodyne plates (20,000/200ml/well) and cultured overnight in complete medium. Cells are quiesced by incubation in serum-free basal medium for 24 hr. After 5-20 minutes treatment with EGF (60ng/ml) or 50 ul of the supernatant produced in Example 14, the medium was removed and 100 ml of extraction buffer ((20 mM HEPES pH 7.5, 0.15 M NaCl, 1% Triton X-100, 0.1% SDS, 2 mM Na₃VO₄, 2 mM Na₄P₂O₇ and a cocktail of protease inhibitors (# 1836170) obtained from Boehringer Mannheim (Indianapolis, IN) is added to each well and the plate is shaken on a rotating shaker for 5 minutes at 4°C. The plate is then placed in a vacuum transfer manifold and the extract filtered through the 0.45 mm membrane bottoms of each well using house vacuum. Extracts are collected in a 96-well catch/assay plate in the bottom of the vacuum manifold and immediately placed on ice. To obtain extracts clarified by centrifugation, the content of each well, after detergent solubilization for 5 minutes, is removed and centrifuged for 15 minutes at 4 degree C at 16,000 x g.

Test the filtered extracts for levels of tyrosine kinase activity. Although many methods of detecting tyrosine kinase activity are known, one method is described here.

-165-

Generally, the tyrosine kinase activity of a supernatant is evaluated by determining its ability to phosphorylate a tyrosine residue on a specific substrate (a biotinylated peptide). Biotinylated peptides that can be used for this purpose include PSK1 (corresponding to amino acids 6-20 of the cell division kinase cdc2-p34) and PSK2 (corresponding to amino acids 1-17 of gastrin). Both peptides are substrates for a range of tyrosine kinases and are available from Boehringer Mannheim.

The tyrosine kinase reaction is set up by adding the following components in order. First, add 10ul of 5uM Biotinylated Peptide, then 10ul ATP/Mg²⁺ (5mM ATP/50mM MgCl₂), then 10ul of 5x Assay Buffer (40mM imidazole hydrochloride, pH7.3, 40 mM beta-glycerophosphate, 1mM EGTA, 100mM MgCl₂, 5 mM MnCl₂, 0.5 mg/ml BSA), then 5ul of Sodium Vanadate(1mM), and then 5ul of water. Mix the components gently and preincubate the reaction mix at 30 degree C for 2 min. Initiate the reaction by adding 10ul of the control enzyme or the filtered supernatant.

The tyrosine kinase assay reaction is then terminated by adding 10 ul of 120mM EDTA and place the reactions on ice.

Tyrosine kinase activity is determined by transferring 50 ul aliquot of reaction mixture to a microtiter plate (MTP) module and incubating at 37 degree C for 20 min. This allows the streptavidin coated 96 well plate to associate with the biotinylated peptide. Wash the MTP module with 300ul/well of PBS four times. Next add 75 ul of anti-phosphotyrosine antibody conjugated to horse radish peroxidase(anti-P-Tyr-POD(0.5u/ml)) to each well and incubate at 37 degree C for one hour. Wash the well as above.

Next add 100ul of peroxidase substrate solution (Boehringer Mannheim) and incubate at room temperature for at least 5 mins (up to 30 min). Measure the absorbance of the sample at 405 nm by using ELISA reader. The level of bound peroxidase activity is quantitated using an ELISA reader and reflects the level of tyrosine kinase activity.

-166-

Example 23: High-Throughput Screening Assay Identifying Phosphorylation Activity

As a potential alternative and/or compliment to the assay of protein tyrosine kinase activity described in Example 22, an assay which detects activation (phosphorylation) of major intracellular signal transduction intermediates can also be used. For example, as described below one particular assay can detect tyrosine phosphorylation of the Erk-1 and Erk-2 kinases. However, phosphorylation of other molecules, such as Raf, JNK, p38 MAP, Map kinase kinase (MEK), MEK kinase, Src, Muscle specific kinase (MuSK), IRAK, Tec, and Janus, as well as any other phosphoserine, phosphotyrosine, or phosphothreonine molecule, can be detected by substituting these molecules for Erk-1 or Erk-2 in the following assay.

Specifically, assay plates are made by coating the wells of a 96-well ELISA plate with 0.1ml of protein G (1ug/ml) for 2 hr at room temp, (RT). The plates are then rinsed with PBS and blocked with 3% BSA/PBS for 1 hr at RT. The protein G plates are then treated with 2 commercial monoclonal antibodies (100ng/well) against Erk-1 and Erk-2 (1 hr at RT) (Santa Cruz Biotechnology). (To detect other molecules, this step can easily be modified by substituting a monoclonal antibody detecting any of the above described molecules.) After 3-5 rinses with PBS, the plates are stored at 4 degree C until use.

A431 cells are seeded at 20,000/well in a 96-well Loprodyne filterplate and cultured overnight in growth medium. The cells are then starved for 48 hr in basal medium (DMEM) and then treated with EGF (6ng/well) or 50 ul of the supernatants obtained in Example 14 for 5-20 minutes. The cells are then solubilized and extracts filtered directly into the assay plate.

After incubation with the extract for 1 hr at RT, the wells are again rinsed. As a positive control, a commercial preparation of MAP kinase (10ng/well) is used in place of A431 extract. Plates are then treated with a commercial polyclonal (rabbit) antibody (1ug/ml) which specifically recognizes the phosphorylated epitope of the Erk-1 and Erk-2 kinases (1 hr at RT). This antibody is biotinylated by standard

-167-

procedures. The bound polyclonal antibody is then quantitated by successive incubations with Europium-streptavidin and Europium fluorescence enhancing reagent in the Wallac DELFIA instrument (time-resolved fluorescence). An increased fluorescent signal over background indicates a phosphorylation by METH1 or METH2 or a molecule induced by METH1 or METH2.

Example 24: Method of Determining Alterations in the METH1 or METH2 Gene

RNA isolated from entire families or individual patients presenting with a phenotype of interest (such as a disease) is be isolated. cDNA is then generated from these RNA samples using protocols known in the art. (See, Sambrook.) The cDNA is then used as a template for PCR, employing primers surrounding regions of interest in SEQ ID NO:1. Suggested PCR conditions consist of 35 cycles at 95 degree C for 30 seconds; 60-120 seconds at 52-58 degree C; and 60-120 seconds at 70 degree C, using buffer solutions described in Sidransky, D. *et al.*, *Science* 252:706 (1991).

PCR products are then sequenced using primers labeled at their 5' end with T4 polynucleotide kinase, employing SequiTherm Polymerase. (Epicentre Technologies). The intron-exon borders of selected exons of METH1 or METH2 is also determined and genomic PCR products analyzed to confirm the results. PCR products harboring suspected mutations in METH1 or METH2 is then cloned and sequenced to validate the results of the direct sequencing.

PCR products of METH1 or METH2 are cloned into T-tailed vectors as described in Holton, T.A. and Graham, M.W., *Nucleic Acids Research* 19:1156 (1991) and sequenced with T7 polymerase (United States Biochemical). Affected individuals are identified by mutations in METH1 or METH2 not present in unaffected individuals.

Genomic rearrangements are also observed as a method of determining alterations in the METH1 or METH2 gene. Isolated genomic clones are nick-translated with digoxigenindeoxy-uridine 5'-triphosphate (Boehringer Mannheim),

-168-

and FISH performed as described in Johnson, Cg. et al., Methods Cell Biol. 35:73-99 (1991). Hybridization with the labeled probe is carried out using a vast excess of human cot-1 DNA for specific hybridization to the METH1 or METH2 genomic locus.

5 Chromosomes are counterstained with 4,6-diamino-2-phenylidole and propidium iodide, producing a combination of C- and R-bands. Aligned images for precise mapping are obtained using a triple-band filter set (Chroma Technology, Brattleboro, VT) in combination with a cooled charge-coupled device camera (Photometrics, Tucson, AZ) and variable excitation wavelength
10 filters. (Johnson, Cv. et al., Genet. Anal. Tech. Appl. 8:75 (1991).) Image collection, analysis and chromosomal fractional length measurements are performed using the ISee Graphical Program System. (Inovision Corporation, Durham, NC.) Chromosome alterations of the genomic region of METH1 or METH2 (hybridized by the probe) are identified as insertions, deletions, and
15 translocations. These METH1 or METH2 alterations are used as a diagnostic marker for an associated disease.

Example 25: Method of Detecting Abnormal Levels of METH1 or METH2 in a Biological Sample

20 METH1 or METH2 polypeptides can be detected in a biological sample, and if an increased or decreased level of METH1 or METH2 is detected, this polypeptide is a marker for a particular phenotype. Methods of detection are numerous, and thus, it is understood that one skilled in the art can modify the following assay to fit their particular needs.

25 For example, antibody-sandwich ELISAs are used to detect METH1 or METH2 in a sample, preferably a biological sample. Wells of a microtiter plate are coated with specific antibodies to METH1 or METH2, at a final concentration of 0.2 to 10 ug/ml. The antibodies are either monoclonal or polyclonal and are produced by the method described in Example 13. The wells are blocked so that non-specific binding of METH1 or METH2 to the well is reduced.

-169-

The coated wells are then incubated for > 2 hours at RT with a sample containing METH1 or METH2. Preferably, serial dilutions of the sample should be used to validate results. The plates are then washed three times with deionized or distilled water to remove unbound METH1 or METH2.

5 Next, 50 ul of specific antibody-alkaline phosphatase conjugate, at a concentration of 25-400 ng, is added and incubated for 2 hours at room temperature. The plates are again washed three times with deionized or distilled water to remove unbound conjugate.

10 Add 75 ul of 4-methylumbelliferyl phosphate (MUP) or p-nitrophenyl phosphate (NPP) substrate solution to each well and incubate 1 hour at room temperature. Measure the reaction by a microtiter plate reader. Prepare a standard curve, using serial dilutions of a control sample, and plot METH1 or METH2 polypeptide concentration on the X-axis (log scale) and fluorescence or absorbance of the Y-axis (linear scale). Interpolate the concentration of the
15 METH1 or METH2 in the sample using the standard curve.

Example 26: Formulating a Polypeptide

20 The METH1 or METH2 composition will be formulated and dosed in a fashion consistent with good medical practice, taking into account the clinical condition of the individual patient (especially the side effects of treatment with the METH1 or METH2 polypeptide alone), the site of delivery, the method of administration, the scheduling of administration, and other factors known to practitioners. The "effective amount" for purposes herein is thus determined by such considerations.

25 As a general proposition, the total pharmaceutically effective amount of METH1 or METH2 administered parenterally per dose will be in the range of about 1ug/kg/day to 10 mg/kg/day of patient body weight, although, as noted above, this will be subject to therapeutic discretion. More preferably, this dose is at least 0.01 mg/kg/day, and most preferably for humans between about 0.01 and

-170-

1 mg/kg/day for the hormone. If given continuously, METH1 or METH2 is typically administered at a dose rate of about 1 ug/kg/hour to about 50 ug/kg/hour, either by 1-4 injections per day or by continuous subcutaneous infusions, for example, using a mini-pump. An intravenous bag solution may also be employed. The length of treatment needed to observe changes and the interval following treatment for responses to occur appears to vary depending on the desired effect.

Pharmaceutical compositions containing METH1 or METH2 are administered orally, rectally, parenterally, intracisternally, intravaginally, intraperitoneally, topically (as by powders, ointments, gels, drops or transdermal patch), buccally, or as an oral or nasal spray. "Pharmaceutically acceptable carrier" refers to a non-toxic solid, semisolid or liquid filler, diluent, encapsulating material or formulation auxiliary of any type. The term "parenteral" as used herein refers to modes of administration which include intravenous, intramuscular, intraperitoneal, intrasternal, subcutaneous and intraarticular injection and infusion.

METH1 or METH2 is also suitably administered by sustained-release systems. Suitable examples of sustained-release compositions include semi-permeable polymer matrices in the form of shaped articles, e.g., films, or microcapsules. Sustained-release matrices include polylactides (U.S. Pat. No. 3,773,919, EP 58,481), copolymers of L-glutamic acid and gamma-ethyl-L-glutamate (Sidman, U. *et al.*, *Biopolymers* 22:547-556 (1983)), poly (2-hydroxyethyl methacrylate) (R. Langer *et al.*, *J. Biomed. Mater. Res.* 15:167-277 (1981), and R. Langer, *Chem. Tech.* 12:98-105 (1982)), ethylene vinyl acetate (R. Langer *et al.*) or poly-D- (-)-3-hydroxybutyric acid (EP 133,988). Sustained-release compositions also include liposomally entrapped METH1 or METH2 polypeptides. Liposomes containing the METH1 or METH2 are prepared by methods known per se: DE 3,218,121; Epstein *et al.*, *Proc. Natl. Acad. Sci. USA* 82:3688-3692 (1985); Hwang *et al.*, *Proc. Natl. Acad. Sci. USA* 77:4030-4034 (1980); EP 52,322; EP 36,676; EP 88,046; EP 143,949; EP 142,641; Japanese Pat. Appl. 83-118008; U.S. Pat. Nos. 4,485,045 and 4,544,545; and EP 102,324.

-171-

Ordinarily, the liposomes are of the small (about 200-800 Angstroms) unilamellar type in which the lipid content is greater than about 30 mol. percent cholesterol, the selected proportion being adjusted for the optimal secreted polypeptide therapy.

5 For parenteral administration, in one embodiment, METH1 or METH2 is formulated generally by mixing it at the desired degree of purity, in a unit dosage injectable form (solution, suspension, or emulsion), with a pharmaceutically acceptable carrier, i.e., one that is non-toxic to recipients at the dosages and concentrations employed and is compatible with other ingredients of the formulation. For example, the formulation preferably does not include oxidizing
10 agents and other compounds that are known to be deleterious to polypeptides.

Generally, the formulations are prepared by contacting METH1 or METH2 uniformly and intimately with liquid carriers or finely divided solid carriers or both. Then, if necessary, the product is shaped into the desired
15 formulation. Preferably the carrier is a parenteral carrier, more preferably a solution that is isotonic with the blood of the recipient. Examples of such carrier vehicles include water, saline, Ringer's solution, and dextrose solution. Non-aqueous vehicles such as fixed oils and ethyl oleate are also useful herein, as well as liposomes.

20 The carrier suitably contains minor amounts of additives such as substances that enhance isotonicity and chemical stability. Such materials are non-toxic to recipients at the dosages and concentrations employed, and include buffers such as phosphate, citrate, succinate, acetic acid, and other organic acids or their salts; antioxidants such as ascorbic acid; low molecular weight (less than
25 about ten residues) polypeptides, e.g., polyarginine or tripeptides; proteins, such as serum albumin, gelatin, or immunoglobulins; hydrophilic polymers such as polyvinylpyrrolidone; amino acids, such as glycine, glutamic acid, aspartic acid, or arginine; monosaccharides, disaccharides, and other carbohydrates including cellulose or its derivatives, glucose, manose, or dextrans; chelating agents such as

-172-

EDTA; sugar alcohols such as mannitol or sorbitol; counterions such as sodium; and/or nonionic surfactants such as polysorbates, poloxamers, or PEG.

METH1 or METH2 is typically formulated in such vehicles at a concentration of about 0.1 mg/ml to 100 mg/ml, preferably 1-10 mg/ml, at a pH of about 3 to 8. It will be understood that the use of certain of the foregoing excipients, carriers, or stabilizers will result in the formation of polypeptide salts.

METH1 or METH2 used for therapeutic administration can be sterile. Sterility is readily accomplished by filtration through sterile filtration membranes (e.g., 0.2 micron membranes). Therapeutic polypeptide compositions generally are placed into a container having a sterile access port, for example, an intravenous solution bag or vial having a stopper pierceable by a hypodermic injection needle.

METH1 or METH2 polypeptides ordinarily will be stored in unit or multi-dose containers, for example, sealed ampoules or vials, as an aqueous solution or as a lyophilized formulation for reconstitution. As an example of a lyophilized formulation, 10-ml vials are filled with 5 ml of sterile-filtered 1% (w/v) aqueous METH1 or METH2 polypeptide solution, and the resulting mixture is lyophilized. The infusion solution is prepared by reconstituting the lyophilized METH1 or METH2 polypeptide using bacteriostatic Water-for-Injection.

The invention also provides a pharmaceutical pack or kit comprising one or more containers filled with one or more of the ingredients of the pharmaceutical compositions of the invention. Associated with such container(s) can be a notice in the form prescribed by a governmental agency regulating the manufacture, use or sale of pharmaceuticals or biological products, which notice reflects approval by the agency of manufacture, use or sale for human administration. In addition, METH1 or METH2 may be employed in conjunction with other therapeutic compounds.

-173-

Example 27: Method of Treating Decreased Levels of METH1 or METH2

The present invention relates to a method for treating an individual in need of a decreased level of METH1 or METH2 activity in the body comprising, administering to such an individual a composition comprising a therapeutically effective amount of METH1 or METH2 antagonist. Preferred antagonists for use in the present invention are METH1 or METH2-specific antibodies.

Moreover, it will be appreciated that conditions caused by a decrease in the standard or normal expression level of METH1 or METH2 in an individual can be treated by administering METH1 or METH2, preferably in the secreted form. Thus, the invention also provides a method of treatment of an individual in need of an increased level of METH1 or METH2 polypeptide comprising administering to such an individual a pharmaceutical composition comprising an amount of METH1 or METH2 to increase the activity level of METH1 or METH2 in such an individual.

For example, a patient with decreased levels of METH1 or METH2 polypeptide receives a daily dose 0.1-100 ug/kg of the polypeptide for six consecutive days. Preferably, the polypeptide is in the secreted form. The exact details of the dosing scheme, based on administration and formulation, are provided in Example 26.

Example 28: Method of Treating Increased Levels of METH1 or METH2

The present invention also relates to a method for treating an individual in need of an increased level of METH1 or METH2 activity in the body comprising administering to such an individual a composition comprising a therapeutically effective amount of METH1 or METH2 or an agonist thereof.

Antisense technology is used to inhibit production of METH1 or METH2. This technology is one example of a method of decreasing levels of METH1 or METH2 polypeptide, preferably a secreted form, due to a variety of etiologies, such as cancer.

For example, a patient diagnosed with abnormally increased levels of METH1 or METH2 is administered intravenously antisense polynucleotides at 0.5, 1.0, 1.5, 2.0 and 3.0 mg/kg day for 21 days. This treatment is repeated after a 7-day rest period if the treatment was well tolerated. The formulation of the antisense polynucleotide is provided in Example 26.

Example 29: Method of Treatment Using Gene Therapy - Ex Vivo

One method of gene therapy transplants fibroblasts, which are capable of expressing METH1 or METH2 polypeptides, onto a patient. Generally, fibroblasts are obtained from a subject by skin biopsy. The resulting tissue is placed in tissue-culture medium and separated into small pieces. Small chunks of the tissue are placed on a wet surface of a tissue culture flask, approximately ten pieces are placed in each flask. The flask is turned upside down, closed tight and left at room temperature over night. After 24 hours at room temperature, the flask is inverted and the chunks of tissue remain fixed to the bottom of the flask and fresh media (e.g., Ham's F12 media, with 10% FBS, penicillin and streptomycin) is added. The flasks are then incubated at 37 degree C for approximately one week.

At this time, fresh media is added and subsequently changed every several days. After an additional two weeks in culture, a monolayer of fibroblasts emerge. The monolayer is trypsinized and scaled into larger flasks.

pMV-7 (Kirschmeier, P.T. *et al.*, *DNA* 7:219-25 (1988)), flanked by the long terminal repeats of the Moloney murine sarcoma virus, is digested with EcoRI and HindIII and subsequently treated with calf intestinal phosphatase. The linear vector is fractionated on agarose gel and purified, using glass beads.

The cDNA encoding METH1 or METH2 can be amplified using PCR primers which correspond to the 5' and 3' end sequences respectively as set forth in Example 5. Preferably, the 5' primer contains an EcoRI site and the 3' primer includes a HindIII site. Equal quantities of the Moloney murine sarcoma virus

-175-

linear backbone and the amplified EcoRI and HindIII fragment are added together, in the presence of T4 DNA ligase. The resulting mixture is maintained under conditions appropriate for ligation of the two fragments. The ligation mixture is then used to transform bacteria HB101, which are then plated onto agar containing kanamycin for the purpose of confirming that the vector contains properly inserted METH1 or METH2.

The amphotropic pA317 or GP+am12 packaging cells are grown in tissue culture to confluent density in Dulbecco's Modified Eagles Medium (DMEM) with 10% calf serum (CS), penicillin and streptomycin. The MSV vector containing the METH1 or METH2 gene is then added to the media and the packaging cells transduced with the vector. The packaging cells now produce infectious viral particles containing the METH1 or METH2 gene (the packaging cells are now referred to as producer cells).

Fresh media is added to the transduced producer cells, and subsequently, the media is harvested from a 10 cm plate of confluent producer cells. The spent media, containing the infectious viral particles, is filtered through a millipore filter to remove detached producer cells and this media is then used to infect fibroblast cells. Media is removed from a sub-confluent plate of fibroblasts and quickly replaced with the media from the producer cells. This media is removed and replaced with fresh media. If the titer of virus is high, then virtually all fibroblasts will be infected and no selection is required. If the titer is very low, then it is necessary to use a retroviral vector that has a selectable marker, such as neo or his. Once the fibroblasts have been efficiently infected, the fibroblasts are analyzed to determine whether METH1 or METH2 protein is produced.

The engineered fibroblasts are then transplanted onto the host, either alone or after having been grown to confluence on cytodex 3 microcarrier beads.

-176-

Example 30: Method of Treatment Using Gene Therapy - In Vivo

Another aspect of the present invention is using *in vivo* gene therapy methods to treat disorders, diseases and conditions. The gene therapy method relates to the introduction of naked nucleic acid (DNA, RNA, and antisense DNA or RNA) METH1 or METH2 sequences into an animal to increase or decrease the expression of the METH1 or METH2 polypeptide. The METH1 or METH2 polynucleotide may be operatively linked to a promoter or any other genetic elements necessary for the expression of the METH1 or METH2 polypeptide by the target tissue. Such gene therapy and delivery techniques and methods are known in the art, see, for example, WO90/11092, WO98/11779; U.S. Patent NO. 5693622, 5705151, 5580859; Tabata H. *et al.* (1997) *Cardiovasc. Res.* 35(3):470-479, Chao, J *et al.* (1997) *Pharmacol. Res.* 35(6):517-522, Wolff J.A. (1997) *Neuromuscul. Disord.* 7(5):314-318, Schwartz, B. *et al.* (1996) *Gene Ther.* 3(5):405-411, Tsurumi Y. *et al.* (1996) *Circulation* 94(12):3281-3290 (incorporated herein by reference).

The METH1 or METH2 polynucleotide constructs may be delivered by any method that delivers injectable materials to the cells of an animal, such as, injection into the interstitial space of tissues (heart, muscle, skin, lung, liver, intestine and the like). The METH1 or METH2 polynucleotide constructs can be delivered in a pharmaceutically acceptable liquid or aqueous carrier.

The term "naked" polynucleotide, DNA or RNA, refers to sequences that are free from any delivery vehicle that acts to assist, promote, or facilitate entry into the cell, including viral sequences, viral particles, liposome formulations, lipofectin or precipitating agents and the like. However, the METH1 or METH2 polynucleotides may also be delivered in liposome formulations (such as those taught in Felgner P.L. *et al.* (1995) *Ann. NY Acad. Sci.* 772:126-139 and Abdallah B. *et al.* (1995) *Biol. Cell* 85(1):1-7) which can be prepared by methods well known to those skilled in the art.

-177-

The METH1 or METH2 polynucleotide vector constructs used in the gene therapy method are preferably constructs that will not integrate into the host genome nor will they contain sequences that allow for replication. Any strong promoter known to those skilled in the art can be used for driving the expression of DNA. Unlike other gene therapies techniques, one major advantage of introducing naked nucleic acid sequences into target cells is the transitory nature of the polynucleotide synthesis in the cells. Studies have shown that non-replicating DNA sequences can be introduced into cells to provide production of the desired polypeptide for periods of up to six months.

The METH1 or METH2 polynucleotide construct can be delivered to the interstitial space of tissues within the an animal, including of muscle, skin, brain, lung, liver, spleen, bone marrow, thymus, heart, lymph, blood, bone, cartilage, pancreas, kidney, gall bladder, stomach, intestine, testis, ovary, uterus, rectum, nervous system, eye, gland, and connective tissue. Interstitial space of the tissues comprises the intercellular fluid, mucopolysaccharide matrix among the reticular fibers of organ tissues, elastic fibers in the walls of vessels or chambers, collagen fibers of fibrous tissues, or that same matrix within connective tissue ensheathing muscle cells or in the lacunae of bone. It is similarly the space occupied by the plasma of the circulation and the lymph fluid of the lymphatic channels. Delivery to the interstitial space of muscle tissue is preferred for the reasons discussed below. They may be conveniently delivered by injection into the tissues comprising these cells. They are preferably delivered to and expressed in persistent, non-dividing cells which are differentiated, although delivery and expression may be achieved in non-differentiated or less completely differentiated cells, such as, for example, stem cells of blood or skin fibroblasts. *In vivo* muscle cells are particularly competent in their ability to take up and express polynucleotides.

For the naked METH1 or METH2 polynucleotide injection, an effective dosage amount of DNA or RNA will be in the range of from about 0.05 g/kg body weight to about 50 mg/kg body weight. Preferably the dosage will be from about

-178-

0.005 mg/kg to about 20 mg/kg and more preferably from about 0.05 mg/kg to about 5 mg/kg. Of course, as the artisan of ordinary skill will appreciate, this dosage will vary according to the tissue site of injection. The appropriate and effective dosage of nucleic acid sequence can readily be determined by those of ordinary skill in the art and may depend on the condition being treated and the route of administration. The preferred route of administration is by the parenteral route of injection into the interstitial space of tissues. However, other parenteral routes may also be used, such as, inhalation of an aerosol formulation particularly for delivery to lungs or bronchial tissues, throat or mucous membranes of the nose. In addition, naked METH1 or METH2 polynucleotide constructs can be delivered to arteries during angioplasty by the catheter used in the procedure.

The dose response effects of injected METH1 or METH2 polynucleotide in muscle *in vivo* is determined as follows. Suitable METH1 or METH2 template DNA for production of mRNA coding for METH1 or METH2 polypeptide is prepared in accordance with a standard recombinant DNA methodology. The template DNA, which may be either circular or linear, is either used as naked DNA or complexed with liposomes. The quadriceps muscles of mice are then injected with various amounts of the template DNA.

Five to six week old female and male Balb/C mice are anesthetized by intraperitoneal injection with 0.3 ml of 2.5% Avertin. A 1.5 cm incision is made on the anterior thigh, and the quadriceps muscle is directly visualized. The METH1 or METH2 template DNA is injected in 0.1 ml of carrier in a 1 cc syringe through a 27 gauge needle over one minute, approximately 0.5 cm from the distal insertion site of the muscle into the knee and about 0.2 cm deep. A suture is placed over the injection site for future localization, and the skin is closed with stainless steel clips.

After an appropriate incubation time (e.g., 7 days) muscle extracts are prepared by excising the entire quadriceps. Every fifth 15 um cross-section of the individual quadriceps muscles is histochemically stained for METH1 or METH2 protein expression. A time course for METH1 or METH2 protein expression may

-179-

be done in a similar fashion except that quadriceps from different mice are harvested at different times. Persistence of METH1 or METH2 DNA in muscle following injection may be determined by Southern blot analysis after preparing total cellular DNA and HIRT supernatants from injected and control mice. The results of the above experimentation in mice can be use to extrapolate proper dosages and other treatment parameters in humans and other animals using METH1 or METH2 naked DNA.

It will be clear that the invention may be practiced otherwise than as particularly described in the foregoing description and examples.

Numerous modifications and variations of the present invention are possible in light of the above teachings and, therefore, are within the scope of the appended claims.

The entire disclosure of all publications (including patents, patent applications, journal articles, laboratory manuals, books, or other documents) cited herein are hereby incorporated by reference.

-180-

What Is Claimed Is:

1. An isolated nucleic acid molecule comprising a polynucleotide selected from the group consisting of:

(a) a polynucleotide encoding a polypeptide comprising amino acids 1 to 950 in SEQ ID NO:2;

(b) a polynucleotide encoding a polypeptide comprising amino acids 2 to 950 in SEQ ID NO:2;

(c) a polynucleotide encoding a polypeptide comprising amino acids 29 to 950 in SEQ ID NO:2;

(d) a polynucleotide encoding a polypeptide comprising amino acids 30 to 950 in SEQ ID NO:2;

(e) a polynucleotide comprising a nucleotide sequence encoding the METH1 polypeptide having the amino acid sequence encoded by the cDNA clone contained in ATCC Deposit No. 209581;

(f) a polynucleotide comprising a nucleotide sequence encoding the mature METH1 polypeptide having the amino acid sequence encoded by the cDNA clone contained in ATCC Deposit No. 209581;

(g) a polynucleotide encoding a polypeptide comprising amino acids 1 to 890 in SEQ ID NO:4;

(h) a polynucleotide encoding a polypeptide comprising amino acids 2 to 890 in SEQ ID NO:4;

(i) a polynucleotide encoding a polypeptide comprising amino acids 24 to 890 in SEQ ID NO:4;

(j) a polynucleotide encoding a polypeptide comprising amino acids 112 to 890 in SEQ ID NO:4;

(k) a polynucleotide comprising a nucleotide sequence encoding the METH2 polypeptide having the amino acid sequence encoded by the cDNA clone contained in ATCC Deposit No. 209582;

-181-

(l) a polynucleotide comprising a nucleotide sequence encoding the mature METH2 polypeptide having the amino acid sequence encoded by the cDNA clone contained in ATCC Deposit No. 209582;

(m) a polynucleotide variant created by altering a polynucleotide of (a), (b), (c), (d), (e), (f), (g), (h), (i), (j), (k), or (l), wherein:

(i) said altering includes a nucleotide insertion, deletion, or substitution, or any combination thereof; and

(ii) the number of alterations is equal to or less than 5% of the total number of nucleotides present in the unaltered polynucleotide;

(n) a polynucleotide encoding amino acids 235 to 459 in SEQ ID NO:2;

(o) a polynucleotide encoding amino acids 460 to 544 in SEQ ID NO:2;

(p) a polynucleotide encoding amino acids 545 to 598 in SEQ ID NO:2;

(q) a polynucleotide encoding amino acids 841 to 894 in SEQ ID NO:2;

(r) a polynucleotide encoding amino acids 895 to 934 in SEQ ID NO:2;

(s) a polynucleotide encoding amino acids 536 to 613 in SEQ ID NO:2;

(t) a polynucleotide encoding amino acids 549 to 563 in SEQ ID NO:2;

(u) a polynucleotide encoding amino acids 214 to 439 in SEQ ID NO:4;

(v) a polynucleotide encoding amino acids 440 to 529 in SEQ ID NO:4;

(w) a polynucleotide encoding amino acids 530 to 583 in SEQ ID NO:4;

-182-

(x) a polynucleotide encoding amino acids 837 to 890 in SEQ ID NO:4;

(y) a polynucleotide encoding amino acids 280 to 606 in SEQ ID NO:4);

5 (z) a polynucleotide encoding amino acids 529 to 548 in SEQ ID NO:4; and

(aa) a nucleotide sequence complementary to any of the nucleotide sequences in (a), (b), (c), (d), (e), (f), (g), (h), (i), (j), (k), (l), (m), (n), (o), (p), (q), (r), (s), (t), (u), (v), (w), (x), (y), or (z).

10 2. An isolated nucleic acid molecule comprising a polynucleotide which encodes the amino acid sequence of an epitope-bearing portion of the METH1 polypeptide of SEQ ID NO:2 or the METH2 polypeptide of SEQ ID NO:4.

15 3. An isolated nucleic acid molecule, comprising a polynucleotide selected from the group consisting of:

(a) 50 contiguous nucleotides of the coding region of SEQ ID NO:1, provided that said nucleotide sequence is not any one of SEQ ID NOs:14-41, or any subfragment thereof; and

20 (b) a nucleotide sequence complementary to the nucleotide sequence in (a).

4. An isolated nucleic acid molecule, comprising a polynucleotide selected from the group consisting of:

25 (a) 50 contiguous nucleotides of the coding region of SEQ ID NO:3, provided that said nucleotide sequence is not SEQ ID NOs:19-22, 24, 42-77, or any subfragment thereof; and

(b) a nucleotide sequence complementary to the nucleotide sequence in (a).

-183-

5. A method for making a recombinant vector comprising inserting an isolated nucleic acid molecule of claim 1 into a vector in operable linkage to a promoter.

6. A recombinant vector produced by the method of claim 5.

5 7. A method of making a recombinant host cell comprising introducing the recombinant vector of claim 6 into a host cell.

8. A recombinant host cell produced by the method of claim 7.

9. A recombinant method for producing a METH1 or METH2 polypeptide, comprising culturing the recombinant host cell of claim 8 under conditions such that said polypeptide is expressed and recovering said polypeptide.
10

10. An isolated polypeptide comprising an amino acid sequence selected from the group consisting of:

- (a) amino acids 1 to 950 in SEQ ID NO:2;
- (b) amino acids 2 to 950 in SEQ ID NO:2;
- 15 (c) amino acids 29 to 950 in SEQ ID NO:2;
- (d) amino acids 30 to 950 in SEQ ID NO:2;
- (d) the amino acid sequence of the METH1 polypeptide having the amino acid sequence encoded by the cDNA clone contained in ATCC Deposit No. 209581;
- 20 (e) the amino acid sequence of the mature METH1 polypeptide having the amino acid sequence encoded by the cDNA clone contained in ATCC Deposit No. 209581;
- (f) amino acids 1 to 890 in SEQ ID NO:4;
- (g) amino acids 2 to 890 in SEQ ID NO:4;
- 25 (h) amino acids 24 to 890 in SEQ ID NO:4;

-184-

(i) amino acids 112 to 890 in SEQ ID NO:4;
(j) an amino acid sequence of the METH2 polypeptide having the amino acid sequence encoded by the METH2 cDNA clone contained in ATCC Deposit No. 209582;

5 (k) an amino acid sequence of the mature METH2 polypeptide having the amino acid sequence encoded by the METH2 cDNA clone contained in ATCC Deposit No. 209582;

(l) the amino acid sequence of a polypeptide variant created by altering a polypeptide of (a), (b), (c), (d), (e), (f), (g), (h), (i), (j), or (k),
10 wherein:

(i) said altering includes an amino acid insertion, deletion, or substitution, or any combination thereof; and

(ii) the number of alterations is equal to or less than 5% of the total number of amino acids present in the unaltered amino acid sequence;

15 (m) amino acids 235 to 459 in SEQ ID NO:2;

(n) amino acids 460 to 544 in SEQ ID NO:2;

(o) amino acids 545 to 598 in SEQ ID NO:2;

(p) amino acids 841 to 894 in SEQ ID NO:2;

(q) amino acids 895 to 934 in SEQ ID NO:2;

20 (r) amino acids 536 to 613 in SEQ ID NO:2;

(s) amino acids 549 to 563 in SEQ ID NO:2;

(t) amino acids 214 to 439 in SEQ ID NO:4;

(u) amino acids 440 to 529 in SEQ ID NO:4;

(v) amino acids 530 to 583 in SEQ ID NO:4;

25 (w) amino acids 837 to 890 in SEQ ID NO:4;

(x) amino acids 280 to 606 in SEQ ID NO:4;

(y) amino acids 529 to 548 in SEQ ID NO:4;

(z) the amino acid sequence of an epitope-bearing portion of any one of the polypeptides of (a), (b), (c), (d), (e), (f), (g), (h), (i), (j), (k), (l),
30 (m), (n), (o), (p), (q), (r), (s), (t), (u), (v), (w), (x), or (y).

-185-

11. The isolated polypeptide of claim 10, which is produced in a recombinant host cell.

12. The isolated polypeptide of claim 11, wherein said recombinant host cell is mammalian.

5 13. An isolated nucleic acid molecule comprising a polynucleotide encoding a METH1 or METH2 polypeptide wherein, except for one to fifty conservative amino acid substitutions, said polypeptide has a sequence selected from the group consisting of:

- 10 (a) amino acids from about 1 to about 950 in SEQ ID NO:2;
- (b) amino acids from about 2 to about 950 in SEQ ID NO:2;
- (c) amino acids from about 29 to about 950 in SEQ ID NO:2;
- (d) amino acids from about 30 to about 950 in SEQ ID NO:2;
- (e) the amino acid sequence of the METH1 polypeptide as encoded by the cDNA clone contained in ATCC Deposit No. 209581;
- 15 (f) the amino acid sequence of the mature METH1 polypeptide as encoded by the cDNA clone contained in ATCC Deposit No. 209581;
- (g) amino acids from about 1 to about 890 in SEQ ID NO:4;
- (h) amino acids from about 2 to about 890 in SEQ ID NO:4;
- (i) amino acids from about 24 to 890 in SEQ ID NO:4;
- 20 (j) amino acids from about 112 to about 890 in SEQ ID NO:4;
- (k) the amino acid sequence of the METH2 polypeptide as encoded by the cDNA clone contained in ATCC Deposit No. 209582; and
- (l) the amino acid sequence of the mature METH2 polypeptide as encoded by the cDNA clone contained in ATCC Deposit No. 209582.

25 14. An isolated polypeptide wherein, except for one to fifty conservative amino acid substitutions, said polypeptide has a sequence selected from the group consisting of:

-186-

- 5 (a) amino acids from about 1 to about 950 in SEQ ID NO:2;
(b) amino acids from about 2 to about 950 in SEQ ID NO:2;
(c) amino acids from about 29 to about 950 in SEQ ID NO:2;
(d) amino acids from about 30 to about 950 in SEQ ID NO:2;
(e) the amino acid sequence of the METH1 polypeptide having
the amino acid sequence encoded by the cDNA clone contained in ATCC Deposit
No. 209581;
(f) the amino acid sequence of the mature METH1 polypeptide
having the amino acid sequence encoded by the cDNA clone contained in ATCC
10 Deposit No. 209581;
(g) amino acids from about 1 to about 890 in SEQ ID NO:4;
(h) amino acids from about 2 to about 890 in SEQ ID NO:4;
(i) amino acids from about 24 to about 890 in SEQ ID NO:4;
(j) amino acids from about 112 to about 890 in SEQ ID NO:4;
15 (k) the amino acid sequence of the METH2 polypeptide having
the amino acid sequence encoded by the cDNA clone contained in ATCC Deposit
No. 209582;
(l) the amino acid sequence of the mature METH2 polypeptide
having the amino acid sequence encoded by the cDNA clone contained in ATCC
20 Deposit No. 209582; and
(m) the amino acid sequence of an epitope-bearing portion of
any one of the polypeptides of (a), (b), (c), (d), (e), (f), (g), (h), (i), (j), (k), or (l).

15. An isolated nucleic acid molecule comprising a polynucleotide at
least 95% identical to a polynucleotide selected from the group consisting of:

- 25 (a) a polynucleotide encoding a polypeptide comprising amino
acids 1 to 950 in SEQ ID NO:2;
(b) a polynucleotide encoding a polypeptide comprising amino
acids 2 to 950 in SEQ ID NO:2;

-187-

(c) a polynucleotide encoding a polypeptide comprising amino acids 29 to 950 in SEQ ID NO:2;

(d) a polynucleotide encoding a polypeptide comprising amino acids 30 to 950 in SEQ ID NO:2;

5 (e) a polynucleotide comprising a nucleotide sequence encoding the METH1 polypeptide having the amino acid sequence encoded by the cDNA clone contained in ATCC Deposit No. 209581;

(f) a polynucleotide comprising a nucleotide sequence encoding the mature METH1 polypeptide having the amino acid sequence encoded by the cDNA clone contained in ATCC Deposit No. 209581;

(g) a polynucleotide encoding a polypeptide comprising amino acids 1 to 890 in SEQ ID NO:4;

(h) a polynucleotide encoding a polypeptide comprising amino acids 2 to 890 in SEQ ID NO:4;

15 (i) a polynucleotide encoding a polypeptide comprising amino acids 24 to 890 in SEQ ID NO:4;

(j) a polynucleotide encoding a polypeptide comprising amino acids 112 to 890 in SEQ ID NO:4;

(k) a polynucleotide comprising a nucleotide sequence encoding the METH2 polypeptide having the amino acid sequence encoded by the cDNA clone contained in ATCC Deposit No. 209582;

(l) a polynucleotide comprising a nucleotide sequence encoding the mature METH2 polypeptide having the amino acid sequence encoded by the cDNA clone contained in ATCC Deposit No. 209582; and

25 (m) a nucleotide sequence complementary to any of the nucleotide sequences in (a), (b), (c), (d), (e), (f), (g), (h), (i), (j), (k), or (l),
wherein

said % identity is calculated using the FASTDB computer program, with the parameters: Matrix=Unitary, k-tuple=4, Mismatch Penalty=1, Joining
30 Penalty=30, Randomization Group Length=0, Cutoff Score=1, Gap Penalty=5,

-188-

Gap Size Penalty=0.05, Window Size=500 or the length of the subject nucleotide sequence, whichever is shorter.

16. An isolated polypeptide comprising a polypeptide having 95% identity to a polypeptide having an amino acid sequence selected from the group consisting of:

(a) amino acids from about 1 to about 950 in SEQ ID NO:2;
(b) amino acids from about 2 to about 950 in SEQ ID NO:2;
(c) amino acids from about 29 to about 950 in SEQ ID NO:2;
(d) amino acids from about 30 to about 950 in SEQ ID NO:2;
(e) the amino acid sequence of the METH1 polypeptide having the amino acid sequence encoded by the cDNA clone contained in ATCC Deposit No. 209581;

(f) the amino acid sequence of the mature METH1 polypeptide having the amino acid sequence encoded by the cDNA clone contained in ATCC Deposit No. 209581;

(g) amino acids from about 1 to about 890 in SEQ ID NO:4;
(h) amino acids from about 2 to about 890 in SEQ ID NO:4;
(i) amino acids from about 24 to about 890 in SEQ ID NO:4;
(j) amino acids from about 112 to about 890 in SEQ ID NO:4;
(k) the amino acid sequence of the METH2 polypeptide having the amino acid sequence encoded by the cDNA clone contained in ATCC Deposit No. 209582; and

(l) the amino acid sequence of the mature METH2 polypeptide having the amino acid sequence encoded by the cDNA clone contained in ATCC Deposit No. 209582;
wherein

said % identity is calculated using the FASTDB computer program, with the parameters: Matrix=PAM 0, k-tuple=2, Mismatch Penalty=1, Joining Penalty=20, Randomization Group Length=0, Cutoff Score=1, Gap Penalty=5,

-189-

Gap Size Penalty=0.05, Window Size=500 or the length of the subject amino acid sequence, whichever is shorter.

17. A method for inhibiting angiogenesis in an individual, comprising administering an effective amount of a polypeptide of claim 10 to said individual.

5 18. A polypeptide comprising the amino acid sequence m-n of SEQ ID NO:2, wherein m is an integer of 1 to 950, and wherein n is an integer of 10 to 950.

10 19. A polypeptide comprising the amino acid sequence m-n of SEQ ID NO:4, wherein m is an integer of 1 to 890, and wherein n is an integer of 10 to 890.

---	--

INDICATIONS RELATING TO A DEPOSITED MICROORGANISM
(PCT Rule 13bis)

A. The indications made below relate to the microorganism referred to in the description on page 32, lines 16-17.	
B. IDENTIFICATION OF DEPOSIT Further deposits are identified on an additional sheet <input checked="" type="checkbox"/>	
Name of depository institution American Type Culture Collection	<div style="border: 1px solid black; padding: 5px; display: inline-block;"> REC'D 26 FEB 1998 WIFO PCT </div>
Address of depository institution (including postal code and country) 10801 University Boulevard formerly at: 12301 Parklawn Drive Manassas, Virginia 20110-2209 Rockville, Maryland 20852 United States of America United States of America	
Date of deposit 15 January 1998	Accession Number 209581
C. ADDITIONAL INDICATIONS (leave blank if not applicable) This information is continued on an additional sheet <input type="checkbox"/>	
DNA plasmid HOUQC17 In respect of those designations in which a European Patent is sought a sample of the deposited microorganism will be made available until the publication of the mention of the grant of the European patent or until the date on which the application has been refused or withdrawn or is deemed to be withdrawn, only by the issue of such a sample to an expert nominated by the person requesting the sample (Rule 28(4) EPC).	
D. DESIGNATED STATES FOR WHICH INDICATIONS ARE MADE (if the indications are not for all designated States)	
E. SEPARATE FURNISHING OF INDICATIONS (leave blank if not applicable)	
The indications listed below will be submitted to the international Bureau later (specify the general nature of the indications, e.g., "Accession Number of Deposit") 	

For receiving Office use only	For International Bureau use only

DNA plasmid HOUCQ17

AUSTRALIA

The applicant hereby gives notice that the furnishing of a sample of a microorganism shall only be effected prior to the grant of a patent, or prior to the lapsing, refusal or withdrawal of the application, to a person who is a skilled addressee without an interest in the invention (Regulation 3.25(3) of the Australian Patents Regulations).

CANADA

The applicant hereby requests that, until either a Canadian patent has been issued on the basis of the application or the application has been refused, or is abandoned and no longer subject to reinstatement, or is withdrawn, the furnishing of a sample of deposited biological material referred to in the application only be effected to an independent expert nominated by the Commissioner of Patents.

DENMARK

The applicant hereby requests that, until the application has been laid open to public inspection (by the Danish Patent Office), or has been finally decided upon by the Danish Patent Office without having been laid open to public inspection, the furnishing of a sample shall only be effected to an expert in the art. The request to this effect shall be filed by the applicant with the Danish Patent Office not later than at the time when the application is made available to the public under Sections 22 and 33(3) of the Danish Patents Act. If such a request has been filed by the applicant, any request made by a third party for the furnishing of a sample shall indicate the expert to be used. That expert may be any person entered on a list of recognized experts drawn up by the Danish Patent office or any person approved by the applicant in the individual case.

FINLAND

The applicant hereby requests that, until the application has been laid open to public inspection (by the National Board of Patents and Registration), or has been finally decided upon by the National Board of Patents and Registration without having been laid open to public inspection, the furnishing of a sample shall only be effected to an expert in the art. The request to this effect shall be filed by the applicant with the International Bureau before the expiration of 16 months from the priority date (preferably on the Form PCT/RO/134 reproduced in annex Z of Volume I of the PCT Applicant's Guide). If such a request has been filed by the applicant, any request made by a third party for the furnishing of a sample shall indicate the expert to be used. That expert may be any person entered on a list of recognized experts drawn up by the National Board of Patents and Registration or any person approved by the applicant in the individual case.

ICELAND

The applicant hereby requests that, until the application has been laid open to public inspection (by the Icelandic Patent Office), or has been finally decided upon by the Icelandic Patent Office without having been laid open to public inspection, the furnishing of a sample shall only be effected to an expert in the art.

DNA plasmid HOUCQ17

Page 2

NETHERLANDS

The applicant hereby requests that until the date of a grant of a Netherlands patent or until the date on which the application is refused or withdrawn or lapsed, the microorganism shall be made available as provided in Rule 31F(1) of the Patent Rules only by the issue of a sample to an expert. The request to this effect must be furnished by the applicant with the Netherlands Industrial Property Office before the date on which the application is made available to the public under Section 22C or Section 25 of the Patents Act of the Kingdom of the Netherlands, whichever of the two dates occurs earlier.

NORWAY

The applicant hereby requests that, until the application has been laid open to public inspection (by the Norwegian Patent Office), or has been finally decided upon by the Norwegian Patent Office without having been laid open to public inspection, the furnishing of a sample shall only be effected to an expert in the art. The request to this effect shall be filed by the applicant with the Norwegian Patent Office not later than at the time when the application is made available to the public under Sections 22 and 33(3) of the Norwegian Patents Act. If such a request has been filed by the applicant, any request made by a third party for the furnishing of a sample shall indicate the expert to be used. That expert may be any person entered on a list of recognized experts drawn up by the Norwegian Patent office or any person approved by the applicant in the individual case.

SINGAPORE

The applicant hereby requests that the furnishing of a sample of a microorganism shall only be made available to an expert. The request to this effect must be filed by the applicant with the International Bureau before the completion of the technical preparations for international publication of the application.

SWEDEN

The applicant hereby requests that, until the application has been laid open to public inspection (by the Swedish Patent Office), or has been finally decided upon by the Swedish Patent Office without having been laid open to public inspection, the furnishing of a sample shall only be effected to an expert in the art. The request to this effect shall be filed by the applicant with the International Bureau before the expiration of 16 months from the priority date (preferably on the Form PCT/RO/134 reproduced in annex Z of Volume I of the PCT Applicant's Guide). If such a request has been filed by the applicant, any request made by a third party for the furnishing of a sample shall indicate the expert to be used. That expert may be any person entered on a list of recognized experts drawn up by the Swedish Patent office or any person approved by the applicant in the individual case.

UNITED KINGDOM

The applicant hereby requests that the furnishing of a sample of a microorganism shall only be made available to an expert. The request to this effect must be filed by the applicant with the International Bureau before the completion of the technical preparations for international publication of the application.
